(54) Title: CELL PERMEABLE PEPTIDES FOR INHIBITION OF INFLAMMATORY REACTIONS AND METHODS OF USE

(57) Abstract: The present invention relates to the delivery of biologically active molecules, such as peptides, into the interior of cells by administering to the cells a complex comprising the molecule linked to an importation competent signal peptide. Such delivery can be utilized, for example, to treat and/or prevent inflammatory conditions, e.g., but not limited to, systemic inflammatory reactions such as endotoxic shock, localized inflammatory reactions such as inflammatory skin diseases and conditions, and inflammatory diseases such as autoimmune diseases.

CROSS REFERENCE TO RELATED APPLICATIONS

This application is a continuation-in-part of U.S. Serial No. 09/450,071, filed November 29, 1999, which is a continuation-in-part of U.S. Serial No. 09/170,754, filed October 13, 1998, which is a continuation of U.S. Serial No. 09/052,784, filed March 31, 1997, which is a continuation of U.S. Serial No. 08/252,852, filed on June 13, 1994, all of which are herein incorporated by reference in their entirety.

FIELD OF THE INVENTION

The present invention relates to biologically active molecules and to methods for delivery of biologically active molecules into the interior of cells by administering to the cells a complex comprising the molecule linked to a signal peptide. The present invention also relates to the development of cell-permeable peptide analogs and to methods for the targeted delivery of these peptide analogs to control systemic inflammatory response syndromes such as endotoxic shock, as well as a broad variety of inflammatory diseases and conditions.

BACKGROUND OF THE INVENTION

Peptides have been developed for many therapeutic uses. For example, diseases currently targeted by new peptide drugs include heart conditions, cancers, endocrine disorders, neurological defects, respiratory conditions, allergies and autoimmune diseases. Although the manufacture of known therapeutic peptides can be achieved by

known methods, i.e., classic synthetic techniques or recombinant genetic engineering, delivery of the peptides into a cell has remained problematic, since they cannot readily cross biological membranes to enter cells. Thus, current methods include permeabilization of the cell membrane, or microinjection into the cell. Both of these
5 methods have serious drawbacks. Permeabilization of cells, e.g., by saponin, bacterial toxins, calcium phosphate, electroporation, etc., can only be practically useful for *ex vivo* methods, and these methods cause damage to the cells. Microinjection requires highly skilled technicians (thus limiting its use to a laboratory setting), it physically damages the cells, and it has only limited applications as it cannot be used to treat for
10 example, a mass of cells or an entire tissue, because one cannot feasibly inject large numbers of cells.

Similarly, delivery of nucleic acids has been problematic. Methods currently employed include the permeabilization described above, with the above-
15 described drawbacks, as well as vector-based delivery, such as with viral vectors, and liposome-mediated delivery. However, viral vectors can present additional risks to a patient, and liposome techniques have not achieved satisfactorily high levels of delivery into cells.

20 Signal peptide sequences,¹ which share the common motif of hydrophobicity, mediate translocation of most intracellular secretory proteins across mammalian endoplasmic reticulum (ER) and prokaryotic plasma membranes through the putative protein-conducting channels.²⁻¹¹ Alternative models for secretory protein transport also support a role for the signal sequence in targeting proteins to membranes.¹²⁻¹⁵

25 Several types of signal sequence-mediated inside-out membrane translocation pathways have been proposed. The major model implies that the proteins are transported across membranes through a hydrophilic protein conducting channel formed by a number of membrane proteins.²⁻¹¹ In eukaryotes, newly synthesized
30 proteins in the cytoplasm are targeted to the ER membrane by signal sequences that are recognized generally by the signal recognition particle (SRP) and its ER membrane

receptors. This targeting step is followed by the actual transfer of protein across the ER membrane and out of the cell through the putative protein-conducting channel (for recent reviews, see references 2-5). In bacteria, the transport of most proteins across the cytoplasmic membrane also requires a similar protein-conducting channel.⁷⁻¹¹ On
5 the other hand, signal peptides can interact strongly with lipids, supporting the proposal that the transport of some secretory proteins across cellular membranes may occur directly through the lipid bilayer in the absence of any proteinaceous channels.¹⁴⁻¹⁵

Thus, though many attempts have been made to develop effective methods for
10 importing biologically active molecules into cells, both *in vivo* and *in vitro*, none has proved to be entirely satisfactory.

SUMMARY OF THE INVENTION

The present invention provides methods and peptides for treating inflammatory
15 diseases and conditions.

For example, the invention provides a method for treating or preventing an inflammatory response in a subject. The method includes administering to the subject a peptide containing an NF- κ B nuclear localization sequence such that nuclear import of
20 a stress-responsive transcription factor is inhibited in a cell of the subject, thereby treating or preventing an inflammatory response in the subject.

The invention also provides a method for treating or preventing septic shock in a subject, including delivering to the subject a compound including a peptide including
25 a nuclear localization sequence of NF- κ B such that nuclear import of NF- κ B is inhibited, thereby treating or preventing septic shock in the subject.

The present invention further provides a method of importing a biologically active molecule into a cell in a subject comprising administering to the subject a
30 complex comprising the molecule linked to an importation competent signal peptide, thereby importing the molecule into the cell of the subject.

Additionally, the instant invention provides a method of importing a biologically active molecule into the nucleus of a cell in a subject comprising administering to the subject a complex comprising the molecule linked to an importation competent signal peptide and a nuclear localization peptide, thereby
5 importing the molecule into the nucleus of the cell of the subject.

The present invention also provides a complex comprising an importation competent signal peptide linked to a biologically active molecule selected from the group consisting of a nucleic acid, a carbohydrate, a lipid, a glycolipid and a therapeutic
10 agent.

The invention also provides peptides for use in the methods of the invention, such as a peptide including the amino acid sequence set forth in SEQ ID NO: 9; a peptide including the amino acid sequence set forth in SEQ ID NO: 12; and a peptide
15 including the amino acid sequence set forth in SEQ ID NO:13.

BRIEF DESCRIPTION OF THE DRAWINGS

The file of this patent contains at least one drawing executed in color. Copies of this patent with color drawing(s) will be provided by the Patent and Trademark Office
20 upon request and upon payment of the necessary fee.

Figure 1 is a graph showing [³H] thymidine incorporation by NIH 3T3 cells stimulated with either (a) SA peptide, SA α peptide, ANL peptide or SM peptide or (b) acidic Fibroblast Growth Factor (aFGF).
25

Figures 2A-2D is a series of graphs demonstrating the improved survival of C57Bl/6 mice treated with the SN50 peptide as compared to untreated or SM-peptide-treated controls. The groups of 5 mice each received intraperitoneal injections of D-galactosamine (20 mg in pyrogen-free saline) without or with peptide (2 mg) 30 min.
30 before LPS from E. coli 0127:B8. The peptide injections were repeated at 30, 90, 150, and 210 minutes following LPS (as shown in Figures 2B and 2C); additional two

injections were administered at 6 and 12 h following LPS (Figure 2D). Surviving mice were euthanized after 72 h. Cumulative results of 2-3 groups are presented in Figure 3A (control mice treated with 5 injection of saline (diluent)); Figure 2B (animals treated with 5 injections of SM peptide); Figure 2C (animals treated with 5 injections of SN50 peptide); and, Figure 2D (animals treated with 7 injections of SN50 peptide).

Figures 3A-3E is a series of graphs illustrating the survival of mice after LPS injection. Female C57Bl/6 mice(20g) were randomly grouped (5 mice per group) and received intraperitoneal injections of LPS (*E. coli* 0127:B5, 800 µg). Treatments included cSN50 (1.5 mg or 0.7 mg) and SM peptide (1.5 mg) given 30 min before LPS, and afterwards at 30,90,150, 210 minutes and 6 hrs and 12 hrs. Figure 3A shows the survival rate where the control (saline) was used. Figure 3B illustrates that rate where cSN50 peptide was administered at 0.7 mg x 7. Figure 3C shows the survival rate where cSN50 peptide was administered at 1.5 mg x 7. Figure 3D illustrates that rate where SM peptide was administered at 1.5 mg x 7. Figure 3E shows the survival rate where cSN50 peptide (1.5 mg) was administered 30 min after endotoxin followed by 0.7 mg injections at 90, 150, 210 min and 6, 12, and 24 hrs.

Figure 4 is a diagram of an electrophoretic mobility shift assay (EMSA) showing the inhibitory effect of the cSN50 peptide of NF-κB nuclear import in T cells.

Figure 5 is a graph showing that death from staphylococcal enterotoxin B (SEB)-induced toxic shock in mice is prevented by inhibition of NF-κB nuclear import by the NF-κB NLS-containing peptide cSN50.

Figures 6A-6D are diagrams showing photomicrographs of liver sections, stained with either hematoxylin and eosin (H & E) or Apop Tag, from untreated SEB-challenged mice and SEB-challenged mice treated with the NF-κB NLS-containing peptide cSN50.

DETAILED DESCRIPTION OF THE INVENTION

The present invention may be understood more readily by reference to the following detailed description of specific embodiments and the Examples and Figures included herein.

5

The present invention provides the discovery that importing exogenous biologically active molecules into intact cells can be engineered by forming a complex by attaching an importation competent signal peptide sequence (also referred to by the synonymous term "cell membrane-permeable hydrophobic region of a signal peptide") to a selected biologically active molecule and administering the complex to the cell. The complex is then imported across the cell membrane by the cell. Thus, the present invention provides a method of importing a biologically active molecule into a cell *ex vivo* or *in vivo* comprising administering to the cell, under import conditions, a complex comprising the molecule linked to an importation competent signal peptide (also known as a cell membrane-permeable hydrophobic region of a signal peptide), thereby importing the molecule into the cell.

As used herein, "biologically active molecule" includes any molecule which if imported into a cell, can have a biological effect. Naturally only those molecules which are of a size which can be imported into the cell are within the scope of the invention. However, since very large proteins (ranging from molecular weights of about 100,000 to around 1 million) are exported by cells (e.g., antibodies, fibrinogen, and macroglobulin), very large proteins can be imported into cells by this method. Therefore, size ranges for proteins from a few amino acids to around a thousand amino acids can be used. A preferable size range for proteins is from a few amino acids to about 250 amino acids. For any molecule, size ranges can be up to about a molecular weight of about 1 million, with a preferable size range being up to a molecular weight of about 25,000, and an even more preferable size range being up to a molecular weight of about 3,000. In addition, only those molecules which can be linked to a signal peptide, either directly or indirectly, are within the scope of the invention. Likewise,

the present invention requires that the complex is administered under suitable conditions for effective import into the cell.

Examples of biologically active molecules include proteins, polypeptides and peptides, which include functional domains of biologically active molecules, such as growth factors, enzymes, transcription factors, toxins, antigenic peptides (as for vaccines), antibodies, and antibody fragments. Additional examples of biologically active molecules include nucleic acids, such as plasmids, coding DNA sequences, mRNAs and antisense RNA molecules, carbohydrates, lipids and glycolipids. Further examples of biologically active molecules include therapeutic agents, in particular those with a low cell membrane permeability. Some examples of these therapeutic agents include cancer drugs, such as Daunorubicin,²⁶ and toxic chemicals which, because of the lower dosage that can be administered by this method, can now be more safely administered.

15 A specific example of a biologically active molecule is the peptide comprising the nuclear location sequence (NLS) of acidic fibroblast growth factor (aFGF), listed herein as SEQ ID NO:2. As demonstrated in the examples below, the NLS of aFGF, when linked to a signal peptide and transported into cells (e.g., the entire peptide listed
20 herein as SEQ ID NO:4), induces a mitogenic response in the cells. Another example of a biologically active molecule is the peptide comprising the NLS of transcription factor NF- κ B subunit p50, listed herein as SEQ ID NO:10. As shown in the examples herein, when a peptide comprising the signal sequence of K-FGF and the NLS of transcription factor NF- κ B p50 subunit, this peptide (called SN50) being listed herein as SEQ ID
25 NO:9, is transfected into cells having transcription factor NF- κ B, the normal translocation of active NF- κ B complex into the nucleus is inhibited. In this manner, cell growth can be inhibited by inhibiting the action of NF- κ B and therefore inhibiting the expression of genes controlled by transcription factor NF- κ B.

30 Yet another example of a biologically active molecule is an antigenic peptide. Antigenic peptides can be administered to provide immunological protection when

imported by cells involved in the immune response. Other examples include immunosuppressive peptides (e.g., peptides that block autoreactive T cells, which peptides are known in the art). Numerous other examples will be apparent to the skilled artisan.

5

- Suitable import conditions are exemplified herein and include cell and complex temperature between about 180°C and about 42°C, with a preferred temperature being between about 22°C and about 37°C. For administration to a cell in a subject the complex, once in the subject, will of course adjust to the subject's body temperature.
- 10 For *ex vivo* administration, the complex can be administered by any standard methods that would maintain viability of the cells, such as by adding it to culture medium (appropriate for the target cells) and adding this medium directly to the cells. As is known in the art, any medium used in this method can be aqueous and non-toxic so as not to render the cells non-viable. In addition, it can contain standard nutrients for
- 15 maintaining viability of cells, if desired. For *in vivo* administration, the complex can be added to, for example, a blood sample or a tissue sample from the patient or to a pharmaceutically acceptable carrier, e.g., saline and buffered saline, and administered by any of several means known in the art. Examples of administration include parenteral administration, e.g., by intravenous injection including regional perfusion.
- 20 through a blood vessel supplying the tissues(s) or organ(s) having the target cell(s), or by inhalation of an aerosol, subcutaneous or intramuscular injection, topical administration such as to skin wounds and lesions, direct transfection into, e.g., bone marrow cells prepared for transplantation and subsequent transplantation into the subject, and direct transfection into an organ that is subsequently transplanted into the
- 25 subject. Further administration methods include oral administration, particularly when the complex is encapsulated, or rectal administration, particularly when the complex is in suppository form. A pharmaceutically acceptable carrier includes any material that is not biologically or otherwise undesirable, i.e., the material may be administered to an individual along with the selected complex without causing any undesirable biological
- 30 effects or interacting in a deleterious manner with any of the other components of the pharmaceutical composition in which it is administered. Administration can be

performed for a time length of about 1 minute to about 72 hours. Preferable time lengths are about 5 minutes to about 48 hours, and even more preferably about 5 minutes to about 20 hours, and even more preferably about 5 minutes to about 2 hours. Optimal time lengths and conditions for any specific complex and any specific target cell can readily be determined, given the teachings herein and knowledge in the art.²⁷ Specifically, if a particular cell type *in vivo* is to be targeted, for example, by regional perfusion of an organ or tumor, cells from the target tissue can be biopsied and optimal dosages for import of the complex into that tissue can be determined *in vitro*, as described herein and as known in the art, to optimize the *in vivo* dosage, including concentration and time length. Alternatively, culture cells of the same cell type can also be used to optimize the dosage for the target cells *in vivo*.

For either *ex vivo* or *in vivo* use, the complex can be administered at any effective concentration. An effective concentration is that amount that results in importation of the biologically active molecule into the cell. Such a concentration will typically be between about 0.5 nM to about 100 μ M (culture medium concentration (*ex vivo*) or blood serum concentration (*in vivo*)). Optimal concentrations for a particular complex and/or a particular target cell can be readily determined following the teachings herein. Thus, *in vivo* dosages of the complex include those which will cause the blood serum concentration of the complex to be about 0.5 nM to about 100 μ M. A preferable concentration is about 2 nM to about 50 μ M. The amount of the complex administered will, of course, depend upon the subject being treated, the subject's age and weight, the manner of administration, and the judgment of the skilled administrator. The exact amount of the complex will further depend upon the general condition of the subject, the severity of the disease/condition being treated by the administration and the particular complex chosen. However, an appropriate amount can be determined by one of ordinary skill in the art using routine optimization given the teachings herein.

Parenteral administration, e.g., regional perfusion, if used, is generally characterized by injection. Injectables can be prepared in conventional forms, such as

liquid solutions, suspensions, or emulsions. A slow release or sustained release system, such as disclosed in U.S. Patent No. 3,710,795, can also be used, allowing the maintenance of a constant level of dosage.

5 Depending on the intended mode of administration (e.g., but not limited to, intravenous, parenteral, transcutaneous, subcutaneous, intramuscular, intracranial, intraorbital, ophthalmic, intraventricular, intracapsular, intraspinal, intracisternal, intraperitoneal, intranasal, intrarectal, intravaginal, aerosol, or oral), the pharmaceutical compositions may be in the form of solid, semi-solid or liquid dosage forms, such as,
10 for example, tablets, suppositories, pills, capsules, powders, liquids, suspensions, lotions, creams, gels, or the like, preferably in unit dosage form suitable for single administration of a precise dosage. The compositions will include, as noted above, an effective amount of the selected drug in combination with a pharmaceutically acceptable carrier and, in addition, may include other medicinal agents, pharmaceutical
15 agents, carriers, adjuvants, diluents, etc.

For solid compositions, conventional nontoxic solid carriers include, for example, pharmaceutical grades of mannitol, lactose, starch, magnesium stearate, sodium saccharin, talc, cellulose, glucose, sucrose, magnesium carbonate, and the like.
20 Liquid pharmaceutically administrable compositions can, for example, be prepared by dissolving, dispersing, etc. an active compound as described herein, and optional pharmaceutical adjuvants in an excipient, such as, for example, water, saline, aqueous dextrose, glycerol, ethanol, and the like, to thereby form a solution or suspension. If desired, the pharmaceutical composition to be administered may also contain minor
25 amounts of nontoxic auxiliary substances such as wetting or emulsifying agents, pH buffering agents and the like. Actual methods of preparing such dosage forms are known, or will be apparent, to those skilled in this art; for example, see Remington's Pharmaceutical Sciences.²⁷

30 The present invention utilizes a complex comprising the selected biologically active molecule linked to an importation competent signal peptide or cell membrane-

permeable hydrophobic region of a signal peptide. As discussed above, the biologically active molecule can be selected from any of a variety of molecules, with its selection being dependent upon the purpose to be accomplished by importing the molecule into the selected cell. An "importation competent signal peptide" or "cell membrane-

5 permeable hydrophobic region of a signal peptide" as used herein, is a sequence of amino acids generally of a length of about 10 to about 50 or more amino acid residues, many (typically about 55-60%) residues of which are hydrophobic such that they have a hydrophobic, lipid-soluble portion.¹ The hydrophobic portion is a common, major motif of the signal peptide, and it is often a central part of the signal peptide of protein

10 secreted from cells. A signal peptide is a peptide capable of penetrating through the cell membrane to allow the export of cellular proteins. The signal peptides of this invention, as discovered herein, are also "importation competent" or "cell-permeable," i.e., capable of penetrating through the cell membrane from outside the cell to the interior of the cell. The amino acid residues can be mutated and/or modified (i.e., to

15 form mimetics) so long as the modifications do not affect the translocation-mediating function of the peptide. Thus the word "peptide" includes mimetics and the word "amino acid" includes modified amino acids, as used herein, unusual amino acids, and D-form amino acids. All importation competent signal peptides encompassed by this invention have the function of mediating translocation across a cell membrane from

20 outside the cell to the interior of the cell. Such importation competent signal peptides could potentially be modified such that they lose the ability to export a protein but maintain the ability to import molecules into the cell. A putative signal peptide can easily be tested for this importation activity following the teachings provided herein, including testing for specificity for any selected cell type.

25

Signal peptides can be selected, for example, from the SIGPEP database, which also lists the origin of the signal peptide.^{30,38} When a specific cell type is to be targeted, a signal peptide used by that cell type can be chosen. For example, signal peptides encoded by a particular oncogene can be selected for use in targeting cells in

30 which the oncogene is expressed. Additionally, signal peptides endogenous to the cell type can be chosen for importing biologically active molecules into that cell type. And

again, any selected signal peptide can be routinely tested for the ability to translocate across the cell membrane of any given cell type according to the teachings herein. Specifically, the signal peptide of choice can be conjugated to a biologically active molecule, e.g., a functional domain of a cellular protein or a reporter construct, and administered to a cell, and the cell is subsequently screened for the presence of the active molecule. The presence of modified amino acids in the signal peptide can additionally be useful for rendering a complex, wherein the biologically active molecule is a peptide, polypeptide or protein, more resistant to peptidase in the subject. Thus these signal peptides can allow for more effective treatment by allowing more peptides to reach their target and by prolonging the life of the peptide before it is degraded. Additionally, one can modify the amino acid sequence of the signal peptide to alter any proteolytic cleavage site present in the original signal sequence for removing the signal sequence. Cleavage sites are characterized by small, positively charged amino acids with no side chains and are localized within about 1 to about 4 amino acids from the carboxy end of the signal peptide.¹

An example of a useful signal peptide is the signal peptide from Capasso fibroblast growth factor (K-FGF),¹⁶⁻¹⁷ listed herein as SEQ ID NO:5. Any signal peptide, however, capable of translocating across the cell membrane into the interior of the selected target cell can be used according to this invention.

By "linked" as used herein is meant that the biologically active molecule is associated with the signal peptide in such a manner that when the signal peptide crosses the cell membrane, the molecule is also imported across the cell membrane. Examples of such means of linking include (1) when the molecule is a peptide, the signal peptide (and a nuclear localization peptide, if desired) can be linked by a peptide bond, i.e., the two peptides can be synthesized contiguously; (2) when the molecule is a polypeptide or a protein (including antibody), the signal peptide (and a nuclear localization peptide, if desired). can be linked to the molecule by a peptide bond or by a non-peptide covalent bond (such as conjugating a signal peptide to a protein with a cross-linking reagent); (3) for molecules that have a negative charge, such as nucleic acids, the

molecule. and the signal peptide (and a nuclear localization peptide, if desired) can be joined by charge-association between the negatively charged molecule and the positively-charged amino acids in the peptide or by other types of association between nucleic acids and amino acids; (4) chemical ligation methods can be employed to create
5 a covalent bond between the carboxy-terminal amino acid of the signal peptide (and a nuclear localization peptide, if desired) and the molecule. Methods (1) and (2) are typically preferred.

Examples of method (1) are shown below wherein a peptide is synthesized, by
10 standard means known in the art,^{24,25} that contains, in linear order from the amino-terminal end, a signal peptide sequence, an optional spacer amino acid region, and a biologically active amino acid sequence. Such a peptide could also be produced through recombinant DNA techniques, expressed from a recombinant construct encoding the above-described amino
15 acids to create the peptide.²⁸

For method (2), either a peptide bond, as above, can be utilized or a non-peptide covalent bond can be used to link the signal peptide with the biologically active polypeptide or protein. This non-peptide covalent bond can be formed by methods standard in the art, such as by conjugating the signal peptide to the polypeptide or
20 protein via a cross-linking reagent, for example, glutaraldehyde. Such methods are standard in the art.²⁹ For method (3) the molecules can simply be mixed with the signal peptide and thus allowed to associate. These methods are performed in the same manner as association of nucleic acids with cationic liposomes.³²⁻³⁴ Alternatively, covalent (thioester) bonds can be formed between nucleic acids and peptides. Such
25 methods are standard in the art.

For method (4), standard chemical ligation methods, such as using chemical cross-linkers interacting with the carboxy-terminal amino acid of the signal peptide, can be utilized. Such methods are standard in the art (see, e.g., Goodfriend,³¹ which uses
30 water-soluble carbodfimide as a ligating reagent) and can readily be performed to link

the carboxy terminal end of the signal peptide to any selected biologically active molecule.

The complex that is administered to a subject can further comprise a liposome.

- 5 Cationic and anionic liposomes are contemplated by this invention, as well as liposomes having neutral lipids. Cationic liposomes can be complexed with the signal peptide and a negatively-charged biologically active molecule by mixing these components and allowing them to charge-associate. Cationic liposomes are particularly useful when the biologically active molecule is a nucleic acid because of the nucleic
- 10 acid's negative charge. Examples of cationic liposomes include lipofectin, lipofectamine, lipofectace and DOTAP.³²⁻³⁴ Anionic liposomes generally are utilized to encase within the liposome the substances to be delivered to the cell. Procedures for forming cationic liposomes encasing substances are standard in the art³⁵ and can readily be utilized herein by one of ordinary skill in the art to encase the complex of this
- 15 invention.

- Any selected cell into which import of a biologically active molecule would be useful can be targeted by this method, as long as there is a means to bring the complex in contact with the selected cell. Cells can be within a tissue or organ, for example,
- 20 supplied by a blood vessel into which the complex is administered. Additionally, the cell can be targeted by, for example, inhalation of the molecule linked to the peptide to target the lung epithelium. Some examples of cells that can be targeted by this inventive method include fibroblasts, epithelial cells, endothelial cells, blood cells and tumor cells, among many. In addition, the complex can be administered directly to a
- 25 tissue site in the body. As discussed above, the signal peptide utilized can be chosen from signal peptides known to be utilized by the selected target cell, or a desired signal peptide can be tested for importing ability given the teachings herein. Generally, however, all signal peptides have the common ability to cross cell membranes due, at least in part, to their hydrophobic character. Thus, in general, a membrane-permeable
- 30 signal peptide can be designed and used for any cell type, since all eukaryotic cell membranes have a similar lipid bilayer.

One particularly useful example is to import an antigenic peptide into cells of the immune system, thereby allowing the antigen to be presented by antigen-presenting cells, and an immune response to the antigen to be developed by the subject. These antigenic peptide-containing complexes can be administered to the subject according to standard methods of administering vaccines, e.g., intramuscularly, subcutaneously or orally, and effectiveness can be measured by subsequent measuring of the presence of antibodies to the antigen. The present invention also provides a method of importing a biologically active molecule into the nucleus of a cell in a subject comprising administering to the subject a complex comprising the molecule linked to an importation competent signal peptide and a nuclear localization peptide, thereby importing the molecule into the nucleus of the cell of the subject. A nuclear localization peptide, as used herein, is a peptide having the function of delivering an intracellular peptide into the nucleus of the cell. Such nuclear localization sequences are known in the art to have this function^{36,37}. An example of a nuclear localization peptide is the nuclear localization sequence of aFGF, listed herein as SEQ ID NO:2. An example of a signal peptide (K-FGF) linked to a nuclear localization peptide (aFGF) is set forth in SEQ ID NO:3. As these examples demonstrate, the nuclear localization peptide sequences can be synthesized as a peptide contiguous with the signal peptide, if desired. Additionally, separate peptides can be linked by any means such as described herein.

The present invention provides a method for treating or preventing sepsis (septic shock) in a subject, e.g., a human subject, comprising delivering to the subject a compound comprising a nuclear localization sequence of NF-kB such that nuclear importation of NF-kB is inhibited in a presently preferred embodiment, one or all of AP-1, NFAT and STAT-1 are also inhibited.

In one embodiment exemplified below, the nuclear localization sequence of NF-kB is delivered into the cells of the subject by linkage to an importation competent signal peptide. See also, Rojas, M. et al., 1998 Nature Biotechnology 16:370-375.

However, the nuclear localization sequence of NF-kB could also be delivered by other means such as by physical methods of introducing proteins into cells (microinjection, electroporation, biolistics); chemical or biological pore formation (digitonin, pore forming proteins and ATP treatment); use of modified proteins (lipidated proteins and
5 bioconjugates, such as with an immunotoxin); and, particle uptake (microspheres, virus mimics, induced pinocytosis). Patton, J., 1998 Nature Biotechnology 16:141-143; Putney and Burke, 1998 Nature Biotechnology 16:153-157 and Fernandez and Bayley, 1998 Nature Biotechnology 16:418-420.

10 Alternatively, one could deliver the nuclear localization sequence of NF-kB by administering to the subject a nucleic acid encoding a nuclear localization sequence of NF-kB. Such a nucleic acid could be delivery for example as naked DNA, with a viral vector, or by means such as cationic liposomes.

15 The present invention also provides a method of importing a biologically active molecule into the nucleus of a cell in a subject comprising administering to the subject a complex comprising the molecule linked to an importation competent signal peptide and a nuclear localization peptide, thereby importing the molecule into the nucleus of the cell of the subject.

20 The present invention also provides a method of regulating growth of a cell in a subject comprising administering to the subject a complex comprising a growth regulatory peptide linked to an importation competent signal peptide to import the growth regulatory peptide into the cell of the subject thereby regulating the growth of
25 the cell. Growth can be stimulated or inhibited depending upon the growth regulatory peptide selected. It is to be noted that the present invention provides regulation of cell growth also by administering a nucleic acid encoding a growth regulatory peptide under functional control of a suitable promoter for expression in a specific target cell, wherein the nucleic acid is complexed with a signal peptide and administered to the target cell.

30

There are numerous growth regulatory peptides known in the art, any of which can be utilized in this invention, if appropriate for the target cell type and the type of regulation desired. The signal peptide facilitates the efficient import of the growth regulatory peptide into the target cell and, once the regulatory peptide is imported, it
5 functions to regulate cell growth in its specific manner. A particularly useful target cell is a tumor cell in which the method can be used to inhibit further aberrant cell growth. Cell growth can be stimulated by administering a growth regulatory peptide comprising the nuclear localization sequence of acidic fibroblast growth factor (aFGF). Cell growth can be inhibited by administering peptides that inhibit growth, for example peptides
10 that inhibit transcription in the cell, such as the NLS of the p50 subunit of transcription factor NF- κ B.

An example of this method is seen below in the examples wherein the growth regulatory peptide stimulates cell growth and comprises the nuclear localization signal
15 of aFGF. As this example demonstrates, the growth regulatory peptide, if desired, can be synthesized contiguously with the signal peptide, though any known method can be utilized to link them. An example of a contiguous peptide is set forth in SEQ ID NO:3 and SEQ ID NO:4. Another example is provided below, wherein a complex (listed as SEQ ID NO:9) comprising the membrane-permeable signal peptide of K-FGF linked to
20 the NLS of transcription factor NF- κ B p50 subunit is administered and inhibits the expression of genes encoding pro-inflammatory mediators.

The invention also provides a method of inhibiting expression in a cell in a subject of a gene controlled by transcription factor NF- κ B comprising administering to
25 the subject a complex comprising an importation competent signal peptide linked to a nuclear localization peptide of an active subunit of NF- κ B complex. Many genes controlled by NF- κ B are known in the art, and others can be readily tested by standard means. Examples of such genes include cytokines and interleukins, such as IL-1, IL-6, granular colony stimulating factor, plasminogen activator inhibitor and procoagulant
30 tissue factor. Additionally, organisms having genes affected by NF- κ B can be inhibited by this method, such organisms including human immunodeficiency virus (HIV) and

cytomegalovirus (CMV). The optimal inhibitory peptide for specific cell types and specific genes can readily be determined by standard methods given the teachings herein. Additionally, the optimal inhibitory peptide for a specific cell type subjected to a specific stimulant can readily be determined.

5

An example is provided herein wherein translocation of the NF- κ B complex to the nucleus in endothelial cells stimulated with lipopolysaccharide,(LPS) is inhibited by a complex comprising a signal peptide linked, to the NLS of subunit p50 of NF- κ B. Presumably, the NLS of subunit p50 interferes with translocation of the complex to the nucleus due to competitive binding. Any cell type subjected to any (or no) stimulus can be readily screened for the optimal inhibitory peptide, i.e., the optimal NLS of a subunit of NF- κ B, for that cell type. For example, for LEII cells, as demonstrated herein, the NLS of p50 is optimal.

15 The subunits of NF- κ B complex are known in the art.⁴³ They include p50, p65 and cellular REL (c-REL). The nuclear localization sequences of these subunits are also known. An "active" subunit of NF- κ B complex, as used herein, means a subunit which, when it is inhibited, causes transcription factor NF- κ B not to function to mediate transcription of genes under its control. The nuclear location peptide used in this method can be a modification of the known NLS of these subunits are long as it retains the function of inhibiting expression of a gene controlled by NF- κ B, as can be readily determined according to the teachings herein and knowledge in the art.

25 The invention further provides a method of stimulating the immune system of a subject comprising administering to the subject a complex comprising an importation competent signal peptide linked to an antigenic peptide. The complex can be administered to the subject by standard means known in the art for administering vaccines. The method can facilitate uptake of the antigen into cells for subsequent antigen presentation and the resultant known cascade of the immune system to result in the stimulation of immunity to the antigen.

30

Furthermore, if known peptides for blocking auto-reactive T cells are linked to a signal peptide and administered to a subject, an immuno-suppressive effect can be stimulated in the subject. Such a method of stimulating immuno-suppression can be used to treat autoimmune diseases such as multiple sclerosis. These blocking peptides
5 can also be administered by known methods for administering peptides, such as methods for administering vaccines.

The invention also provides a complex comprising a biologically active molecule linked to an importation competent signal peptide and to a nuclear
10 localization peptide. The linkage can be made as described above or otherwise known in the art. Though, as described above, any signal peptide and any nuclear localization sequence can be utilized, such a complex is exemplified by the amino acid sequences set forth in SEQ ID NO:3 and SEQ ID NO:4, which contain the K-FGF signal peptide (SEQ ID NO:5) linked to the aFGF nuclear localization peptide (SEQ ID NO:2).

15

The invention further provides a complex comprising an importation competent signal peptide linked to biologically active molecule selected from the group consisting of a nucleic acid, a carbohydrate, a lipid, a glycolipid and a therapeutic agent. This complex can further comprise a liposome. These complexes can be formed as described
20 above. Liposomes can be selected as described above. The complex can be placed in a pharmaceutically acceptable carrier.

Treatment of Inflammatory Diseases and Conditions

The methods and peptides of the present invention can be used to treat any
25 inflammatory disease or condition involving pro-inflammatory cytokines.

For example, the invention provides methods for treating or preventing an inflammatory response in a subject. These methods include administering to the subject a peptide containing an NF-kB nuclear localization sequence such that nuclear
30 import of a stress-responsive transcription factor is inhibited in a cell of the subject, thereby treating or preventing an inflammatory response in the subject.

As exemplified below, the stress-responsive transcription factor can be NF-kB, AP-1, NFAT, or STAT-1. The NF-kB nuclear localization sequence can include the amino acid sequence Gln-Arg-Lys-Arg-Gln-Lys or the amino acid sequence Val-Gln-Arg-Lys-Arg-Gln-Lys-Leu-Met-Pro. Also, the peptide containing the NF-kB nuclear
5 localization sequence can further include a cell membrane-permeable hydrophobic region of a signal peptide.

The peptides of the invention include cyclic peptides that contain a cell membrane-permeable hydrophobic region of a signal peptide and an NF-kB nuclear
10 localization sequence. One specific example of such a cyclic peptide is cSN50 (SEQ ID NO: 12). For example, the cyclic peptides of the invention can include a cyclized NF-kB nuclear localization sequence having the amino acid sequence Cys-Xaa-Xaa-Gln-Arg-Lys-Arg-Gln-Lys-Xaa-Xaa-Cys (Cys-Xaa-Gln-Arg-Lys-Arg-Gln-Lys-Xaa-Xaa-Cys), wherein Xaa is any amino acid (for example, any naturally occurring amino
15 acid, or a synthetic variant thereof). Moreover, one or more amino acids of the cyclic peptides can be a D-amino acid. The Xaa residues surrounding the NF-kB nuclear localization sequence of the cyclic peptides can all correspond to the sequence found in cSN50 or the sequence found in the naturally occurring NF-kB nuclear localization sequence, or only one Xaa, or any combination of two Xaas, three Xaas, four Xaas, or
20 all five Xaas may diverge from the sequences found in cSN50 or in the naturally occurring NF-kB nuclear localization sequence. Such cyclic peptide Xaa variants are made by methods that are well known in the art and tested as described herein, or using any other known assay for measuring inflammatory responses or nuclear import of a stress-responsive transcription factor. The present invention provides methods for
25 identifying cyclic peptides for treating or preventing an inflammatory response in a subject, using any of the methods described herein (see, e.g., Example III).

Cyclization can be achieved by other means, as described in Example V below. Cyclic peptides can also be produced by cyclization via residues (e.g., cysteine) at the
30 amino and carboxy termini of the peptide as described in Example V below. The cell membrane-permeable hydrophobic region of a signal peptide can include a Kaposi

Fibroblast Growth Factor signal peptide hydrophobic region having the amino acid sequence Ala-Ala-Val-Ala-Leu-Leu-Pro-Ala-Val-Leu-Ala-Leu-Leu-Ala-Pro or an integrin beta-3 signal peptide hydrophobic region having the amino acid sequence Val-Thr-Val-Leu-Ala-Leu-Gly-Ala-Leu-Ala-Gly-Val-Gly-Val-Gly.

5

The methods and peptides of the invention can be used to treat or prevent inflammatory responses caused by a microbe (or a toxin from a microbe), e.g., a bacterium (e.g., a Gram-positive or Gram-negative bacterium), a rickettsia, a virus, a fungus, or a protozoan. For example, the bacterium can be a Gram-negative bacterium such as *Escherichia coli*, *Salmonella typhimurium*, *Salmonella typhosa* and other *Salmonella* species, or *Pseudomonas aeruginosa* and other *Pseudomonas* species; or the bacterium can be a Gram-positive bacterium, such as a species of *Staphylococcus*, *Streptococcus*, and *Pneumococcus* that causes an inflammatory response, for example, as a result of food poisoning or a noscomial infection). Other examples of microbial infections that cause inflammatory responses that can be treated or prevented by the methods of the invention include rickettsia, e.g., *Rickettsia rickettsiae*; viruses, e.g., Ebola virus, Dengue hemorrhagic fever virus, West Nile encephalitis virus, and hepatitis virus A, B, or C; fungi, e.g., *Candida albicans*, *Cryptococcus neoformans*, and *Histoplasma capsulatum*), and protozoans e.g., *Plasmodium falciparum* and other species of *Plasmodium* that cause malaria.

The methods and peptides of the invention can be used to treat or prevent inflammatory reactions triggered by toxins, such as any toxin produced by a microbe that causes an inflammatory response, for example, but not limited to, lipopolysaccharide, or a superantigen (e.g., *Staphylococcus enterotoxin A* or *B*, streptococcal pyrogenic toxins and *M* proteins, or any superantigen produced by a microbe). The methods can also be used to treat or prevent any inflammatory reaction induced by a superantigen. Other examples of toxins that trigger inflammatory reactions that can be treated by the methods of the invention include plant toxins, e.g., poison ivy or poison oak, nickel, latex, environmental toxins (such as toxic chemicals) or allergens that invoke an inflammatory response upon skin contact or inhalation. For

example, inhalation of toxins can cause Adult Respiratory Distress Syndrome (which can also result from septic shock and other medical conditions), which can be treated or prevented using the methods of the invention.

5 Both systemic and localized inflammatory responses can be treated or prevented using the methods and peptides of the invention. For example, the methods can be used to treat or prevent systemic inflammatory response syndrome and/or sepsis syndrome, which, if untreated, can lead to septic shock, which may ultimately result in death. As is well known in the art and described in the Examples below, bacteremias resulting
10 from Gram-negative or Gram-positive infections can cause sepsis syndrome leading to septic shock. One well known example of this process is Toxic Shock Syndrome caused by species of Gram-positive bacteria such as *Staphylococcus* or *Staphylococcus*.

15 The methods and peptides of the invention can also be used to treat or prevent inflammatory responses that affect the function of specific organs or organ systems, for example, but not limited to, the liver, bowel, kidney, joints, skin, pancreas, central nervous system, peripheral nervous system, bladder, or reproductive organs. In some cases, the inflammatory response is caused by an inflammatory disease, for example, an
20 autoimmune disease. Examples of such autoimmune diseases include, but are not limited to, inflammatory bowel disease, Crohn's disease, glomerulonephritis, multiple sclerosis, lupus erythematosus, rheumatoid arthritis, psoriasis, or juvenile diabetes. The methods and peptides of the invention can also be used to treat chronic or acute inflammatory diseases and conditions of the skin, for example, psoriasis, eczema, or
25 contact dermatitis.

 Moreover, cellular apoptosis induced by inflammatory conditions involving pro-inflammatory cytokines and/or nuclear import of stress-responsive transcription factors (such as NF-kB, AP-1, NFAT, or STAT-1) can be inhibited, minimized, or
30 prevented using the methods of the invention. For example, as described in the Examples below, apoptosis of liver cells resulting from septic shock can be inhibited by

the present methods and peptides. These can be used to inhibit liver cell apoptosis caused by other types of acute liver injury resulting from inflammation, for example, toxins that poison the liver (one example being poisoning by acetaminophen) or viruses (such as hepatitis virus).

5

The invention provides a method for treating or preventing septic shock in a subject, including delivering to the subject a compound including a peptide including a nuclear localization sequence of NF- κ B such that nuclear import of NF- κ B is inhibited, thereby treating or preventing septic shock in the subject. The peptide used in this and
10 any other method of the invention can further include a cell membrane-permeable hydrophobic region of a signal peptide. Furthermore, the present method may also inhibit the nuclear import of a member selected from the group consisting of AP-1, NFAT and STAT-1, the present method may also inhibit the nuclear import of each of AP-1, NFAT and STAT1.

15

The invention also provides a method of importing a biologically active molecule into the nucleus of a cell in a subject, including administering to the subject a complex including the molecule linked to a cell membrane-permeable hydrophobic region of a signal peptide and a nuclear localization peptide, thereby importing the
20 molecule into the nucleus of the cell of the subject. For example, the molecule can be linked to a peptide including the amino acid sequence set forth in SEQ ID NO:12 or SEQ ID NO:13.

In addition, the invention provides a method for treating or preventing a
25 systemic inflammatory response in a subject, wherein the systemic inflammatory response involves import of a stress-responsive transcription factor into the nucleus of a cell in the subject, including administering to the subject a peptide including a nuclear localization sequence of NF- κ B, thereby treating or preventing the systemic inflammatory response in the subject.

30

The invention further provides a method of inhibiting the import of a stress-responsive transcription factor into the nucleus of a cell, including administering to the cell a peptide including a nuclear localization sequence of NF- κ B, thereby inhibiting the import of the stress-responsive transcription factor into the nucleus of the cell. If
5 the cell is within a subject, the peptide can be administered to the subject using routine methods. In one particular example of the present method, the cell is a liver cell and administration of the peptide to the liver cell inhibits apoptosis of the liver cell. The peptide used in this method can for example, be a cyclic peptide, such as a cyclic peptide including the amino acid sequence set forth in SEQ ID NO: 12.

10

The invention further provides a complex including a cell membrane-permeable hydrophobic region of a signal peptide linked to a biologically active molecule selected from the group consisting of a nucleic acid, a carbohydrate, a lipid, a glycolipid and a therapeutic agent. In a particular example, the molecule can be linked to a cyclic
15 peptide, for example, a cyclic peptide including the amino acid sequence set forth in SEQ ID NO: 12.

The invention also provides peptides, such as a peptide including the amino acid sequence set forth in SEQ ID NO: 9; a peptide including the amino acid sequence set
20 forth in SEQ ID NO: 12; and a peptide including the amino acid sequence set forth in SEQ ID NO: 13. These and other peptides may be used in the methods of the invention.

Statement Concerning Utility

The present method, which provides an effective method for importing
25 biologically active molecules into cells, has many uses, both *in vivo* and *ex vivo*. Specific utilities using the method are apparent and are exemplified as follows. *In vivo*, the method can be used to deliver into cells therapeutic molecules, such as peptides and proteins to regulate aberrant functions or to supply deficient cells; DNA for gene therapy (e.g., to provide the CFTR gene in cystic fibrosis patients); RNA for antisense
30 therapy (e.g., to inhibit growth as in inhibiting expression in cancer cells); and therapeutic agents such as cancer drugs or toxic chemicals (which can be administered

in lower dosages with this method as compared to previous methods not utilizing a signal peptide to more efficiently enter the cells). *Ex vivo*, the method allows efficient transfection of cells without performing cell-damaging procedures. Therefore, this method is useful *ex vivo* in any method that utilizes transfection, such as transecting
5 reporter genes into cells to screen for compounds that affect expression of the reporter gene, and for transfecting bone marrow cells, blood cells, cells of an organ for subsequent transplantation into a subject or culture cells, with a gene to effect protein expression in the cells.

10 More specifically, this method can be used for anti-thrombotic therapy by administering functional domains of known cell receptors which mediate aggregation of platelets, by competitive binding. Additionally, the method can be used for immunosuppression in autoimmune diseases by introducing immunosuppressive peptides into cells involved in the immune response. Furthermore, growth inhibitors
15 can be administered by this method to tumor cells to treat, for example, cancer cells.

This method can also be used to facilitate the absorption of biologically active molecules from, e.g., the mouth, stomach or intestinal tract by facilitating movement of the molecules into the connective tissue beneath the lining of the digestive tract. Also,
20 by allowing one to design signal peptides with modified amino acids, one can stabilize biologically active peptides by making them more resistant to peptidases and therefore also prolong the action of the peptide.

In addition, methods of treating sepsis are also provided.
25

As used herein, "a" can mean one or more, depending on the context in which it is used.

The invention is more particularly described in the following examples which
30 are intended as illustrative only since numerous modifications and variations therein will be apparent to those skilled in the art.

EXAMPLE I

The peptides used herein were synthesized by a step-wise solid-phase peptide synthesis approach²⁴ and purified by high performance liquid chromatography using
5 C₁₈ reverse phase column as described.²⁵ The exact molecular weights of the purified peptides were confirmed by mass spectrometry analysis.

Amino acid residues 1-16 of the SM peptide were patterned after the predicted signal peptide sequence of K-FGF^{16,17} (listed separately herein as SEQ ID NO:5),
10 residues 17-19 were designed as a spacer, and residues 20-26 contain an epitope tag recognized by antibody (see SEQ ID NO:1). Amino acid residues 1-19 of the SA peptide are identical to those of the SM peptide. However, its carboxyl terminal residues 20-26 are same as the sequence of the ANL peptide (SEQ ID NO:2), which is derived from the nuclear localization sequence of acidic FGF.¹⁸ The SA peptide is
15 listed as SEQ ID NO:3. The amino acid sequence of the SA α peptide was the same as that of the SA peptide except it had a two amino acid residue extension (Met-Pro) at the carboxyl terminus, which created an epitope (Leu-Met-Pro) for anti-SM peptide antibody. The SA α peptide is listed herein as SEQ ID NO:4.

20 Membrane-Permeable Signal Sequence Peptide (SM Peptide)

A 26-residue peptide (referred to as SM, listed herein as SEQ ID NO:1) that contained the predicted signal sequence of Kaposi fibroblast growth factor¹⁶⁻¹⁷ (K-FGF) was chemically synthesized. An indirect immunofluorescence assay using antibody against epitope tag-containing SM peptide was employed to follow translocation of the
25 SM peptide to the intracellular compartments of NIH 3T3 cells. A polyclonal anti-SM peptide antibody against the SM peptide-keyhole limpet haemocyanin conjugate (Pierce) was raised in rabbits and reacted with SM peptide in ELISA (titer > 1:30,000). The intracellular SM peptide was detected by an indirect immunofluorescence assay using affinity-purified anti-SM peptide IgG and rhodamine-labeled anti-rabbit antibody
30 (Kirkegaard & Perry). Briefly, confluent NIH 373 cells on the chamber slides (Nunc) were treated with either 0.5 ml SM peptide solution (100 μ g ml⁻¹) in DMEM containing

10% FBS or with 0.5 ml DMEM containing 10% FBS only for 30 minutes at 37°C. The cells were fixed with 3.5% paraformaldehyde solution in PBS followed by 0.25% Triton X-100 in PBS and then treated with 1:20 anti-SM peptide IgG in PBS containing 0.5% bovine serum albumin (BSA) for 1.5 h. The intracellular SM peptide-antibody complexes were visualized by subsequent incubation with a rhodamine-labeled anti-rabbit polyclonal antibody for 1 h. In control systems, anti-SM peptide antibody was preabsorbed with the SM peptide. Intracellular localization of the SA α peptide was detected by immunofluorescence assay using affinity-purified anti-SM peptide IgG as described above for SM peptide. Following incubation of cells with SM peptide, intracellular deposits were observed in almost all cells. A ten-step z-position sectional scanning of the SM peptide-treated cells by the confocal laser scanning microscopy (CLSM) affirmed that these deposits were intracellular. Immunodetection of the SM peptide was specific because cells incubated with the peptide-antibody complex showed no evidence of intracellular peptide. Likewise, cells not exposed to SM peptide or cells exposed to SM peptide followed by the secondary antibody alone were negative. If cells were fixed with paraformaldehyde before peptide treatment, the cellular import of SM peptide was prevented.

To determine the rate of SM peptide import across cell membranes, a kinetic experiment was carried out with the SM peptide-treated NIH 3T3 cells. NIH 3T3 cells were treated at 37°C with 0.5 ml SM peptide at 100 $\mu\text{g mL}^{-1}$ in DMEM containing 10% FBS for 1, 5, 15, 30, 60 and 120 minutes. Intracellular SM peptide deposits were detected by indirect immunofluorescence assay as described above. The intracellular staining of intracellular SM peptide was observed during the first 5 minute interval and plateaued at about 30 minutes, indicating that the signal sequence-mediated peptide import into cells is rapid. The 30-minute time point was therefore selected to determine the optimal peptide concentrations for detectable import.

To determine the optimal peptide concentration, NIH 3T3 cells were treated for 30 minutes at 37°C with 0.5 ml SM peptide solution in DMEM containing 10% FBS at the following concentrations: 0, 2, 10, 50, 100, and 150 $\mu\text{g mL}^{-1}$. Intracellular

localization of the SM peptide was detected by indirect immunofluorescence assay as described above. Indirect immunofluorescence assay demonstrated detectable peptide in the form of intracellular punctate deposits when the cells were exposed to 2 $\mu\text{g/ml}$ (about 800 nM) of peptide. The cellular import was concentration-dependent and
5 reached a plateau between 50 $\mu\text{g/ml}$ and 100 $\mu\text{g/ml}$.

Transport of the SM peptide across the cell membrane was temperature-dependent. No immunofluorescence staining was observed when the cells were treated for 30 minutes with 100 $\mu\text{g/ml}$ of the peptide at 4°C, whereas, cells treated at either
10 22°C or 37°C showed numerous punctate deposits. Accordingly, cellular import of the SM peptide resumed when the incubation temperature shifted from 4°C to 37°C.

Moreover, this signal sequence-mediated import is not limited to NIH 3T3 cells. The intracellular localization of SM peptide has been used in baby hamster kidney-21
15 cells, human umbilical vein endothelial cells (HUVF-Cs) and rodent endothelial cell line (LE-II), by the above indirect immunofluorescence assay, with the same results as with NIH 3T3 cells.

Membrane-Permeable Signal Peptide (SKP peptide)

20 Intracellular localization of the membrane-permeable peptide was also shown by treatment of cells with proteases following peptide import. For this experiment, 41-residue peptide (referred to as SEP and listed herein as SEQ ID NO:6) that contained the same hydrophobic sequence as SM peptide followed by the sequence of K-FGF(129-153) was designed and synthesized. The latter was present in KP peptide not
25 containing hydrophobic sequence that served as the control for the membrane-permeable SKP peptide. Both peptides possess tyrosine residues, therefore they were radiolabeled with ^{125}I and examined for their ability to translocate into intact NIH 3T3 cells, as described below. Substantial radioactivity was detected in the ^{125}I -SKP
30 peptide-treated cells but not in ^{125}I -KP peptide-treated cells, indicating that the import of SKP peptide into cells was selectively achieved due to the presence of hydrophobic, membrane-permeable sequence. The intracellular ^{125}I -SKP peptide was resistant to the

action of proteases. After treatment of cells containing ^{125}I -SKP peptide with pronase or trypsin, no significant loss of cell-associated radioactivity was observed, suggesting that the ^{125}I -SKP peptide was located in intracellular compartments (Table 1). The import of membrane-permeable peptide was not dependent on ATP as high energy
 5 source because cells depleted of about 95% of ATP showed a similar ^{125}I -SKP peptide uptake as compared to ATP-positive cells (Table 1).

Both SKP and KP peptides were radiolabeled with ^{125}I by the Iodogen method (Pierce). The specific activities of both peptides were similar (2.5×10^4 cpm/ng). NIH
 10 3T3 cells were subcultured on a 60-mm dish and incubated at 37°C for 3 days. The confluent monolayers (1.6×10^6 cells) on each dish were then washed twice with PBS and treated with 15 ng of ^{125}I -SKP or ^{125}I -KP peptide at 37°C , for the indicated time. The cells were washed eight times with PBS and twice with 2 M NaCl buffer (pH 7.5) until no radioactivity could be detected in the washings. The washed cells were lysed
 15 in lysis buffer (10 mM Tris-HCl, pH 7.0, 0.1 mM EDTA, 1 mM phenylmethylsulphonyl fluoride, 1 mM dithiothreitol, and 1% Triton X-100) and the radioactivity in the cell lysates was counted in a Packard auto-gamma counter. In some experiments, the washed cells were further treated with pronase (1 mg/ml) or trypsin (0.05%) solution in DMEM for 5 min at 37°C . The supernatants and cells were separated and their
 20 radioactivities were counted separately. For ATP depletion assay, cells were incubated with $5\mu\text{g/ml}$ antimycin, 6.5 mM 2-deoxyglucose, and 10 mM glucono- δ -lactone in DMEM for 2 h at 37°C before addition of ^{125}I -SKP peptide. The levels of ATP in ATP-depleted cells and normal cells were determined by ATP bioluminescent assay kit (Sigma). No measurable ATP was observed in ATP-depleted cells.

25

TABLE 1

IMPORT OF ^{125}I -SKP PEPTIDE INTO ATP-DEPLETED NIH 3T3
 CELLS AND EFFECT OF PROTEASES ON CELL-ASSOCIATED
 ^{125}I -SKP PEPTIDE

30

<u>ATP Depletion</u>	<u>Counts in cells (cpm/1.6×10^6 cells)</u>
Untreated cells	$20,189 \pm 2,109$

APT-depleted cells		22,266 ± 3,602
<u>Protease Treatment</u>	<u>Counts in cell lysates</u>	Counts in supernatants
Untreated cells	21,323 ± 853	2,966 ± 838
Pronase	21,791 ± 1,953	1,979 ± 75
5 Trypsin	23,193 ± 3 10	655 ± 70

For ATP depletion assay, confluent NIH 3T3 cells (1.6×10^6 cells) in each dish were treated with or without ATP depleting reagents (antimycin, 2deoxyglucose, and glucono- δ -lactone) for 2 h at 37°C. Cells were then treated with 15 ng of 125 I-SKP peptide for 30 min at 37°C. After complete removal of extracellular 125 I-labeled peptides, the radioactivity in the cell lysates was counted. For the assay using proteases, cells were treated with 125 I-SKP peptide and washed as described above. The 125 I-SKF peptide-associated cells were then treated with pronase (1 mg/ml), trypsin (0.05%), or diluent for 5 min at 37°C. The radio-activities in the cell lysates and supernatants were counted separately. Data in Table 1 represent the mean the mean \pm SEM of triplicate determinations of a single experiment. The experiment was repeated three times with similar results.

20 Membrane-Permeable Signal Peptide with Functional Peptide Cargo (SA peptide)

Having demonstrated the feasibility of the cellular import of signal sequence-containing peptides, functional cargo in the form of a sequence responsible for the nuclear localization of cellular proteins was linked to a signal peptide. The nuclear localization sequence (NLS) of acidic FGF (aFGF), because it has previously been reported to play an essential role in aFGF mitogenic activity, was utilized.¹⁸ It had previously been shown that a mutant aFGF with deletion in its NLS region Asn-Tyr-Lys-Lys-Pro-Lys-Leu (NYKKPKL), listed herein as SEQ ID NO:2, failed to stimulate DNA synthesis and cell proliferation *in vitro* although it could still bind to the FGF receptor and induce intracellular receptor-mediated tyrosine phosphorylation and c-fos expression.¹⁸ Additionally, a recent study¹⁹ of nuclear transport of aFGF suggested that

translocation of aFGF to the nucleus was necessary for stimulating DNA synthesis by aFGF *in vitro*.

A 26-residue hybrid peptide (referred to as SA, listed herein as SEQ ID NO:3) was designed and synthesized. It contains the signal sequence of K-FGF^{16,17} at its amino terminal region (residues 1 - 16 of SEQ ID NO:3) and a "functional cargo" in the form of a nuclear localization sequence (NLS) of aFGF¹⁸ at its carboxyl terminal region (residues 20-26 of SEQ ID NO:3), separated by a spacer region of Ala-Ala-Ala (residues 17-19 of SEQ ID NO:3). Thus, the SA peptide differs from the SM peptide only in its 7-residue carboxyl terminal "cargo" region. A functional assay was performed in which SA peptide was able to induce a mitogenic response of NIH 3T3 cells measured by [³ H]thymidine incorporation in a manner similar to aFGF bearing, the same NLS.¹⁸

In this functional assay, confluent 3T3 cells grown initially in DMEM containing 10% FBS were transferred to a low serum medium (DMEM containing 0.5% FBS) for 2 days. The test peptides, either SA peptide, SA α peptide, ANL peptide, or SM peptide, or aFGF, were added to a fresh low serum medium at the indicated concentrations at 37°C. After 16 hours, [³ H]thymidine was added and 4 hours later, the cells were washed with PBS, treated with trichloroacetic acid, solubilized with 0.15 M NaOH, and the radioactivity was determined in a liquid scintillation counter.

As shown in Fig. 1a, SA peptide stimulated [³ H]thymidine incorporation 6-fold, while aFGF induced approximately an 8-fold stimulation in the same assay (Fig. 1b). Bars represent the mean \pm S.E.M. of at least three independent experiments done in triplicate and calculated as multiplicity of counts in the tested sample over the control sample. SA peptide within the concentration range used (0 to 46 μ M) was not cytotoxic as determined by staining with fluorescein diacetate/ethidium bromide.²⁰

Mitogenic Activity of the SA Peptide

To determine whether the mitogenic activity of SA peptide required its full length sequence, two control peptides were examined in the same assay. They are the SM peptide containing signal peptide listed herein as SEQ ID NO:1) and a 7-residue peptide (referred to as ANL, listed herein as SEQ ID NO:2) representing the NLS of aFGF. Neither control peptide showed any significant mitogenic activity when tested within comparable concentration ranges (Fig. 1a). These results suggest that neither the signal sequence alone (SM peptide) nor the nuclear localization sequence alone (ANL peptide) was sufficient for mitogenesis. SA peptide therefore was effective in mitogenesis because it contained both the signal peptide sequence of K-FGF (for import into the cell) and nuclear localization sequence of aFGF (for mitogenic activity).

To further confirm the mitogenic activity of the SA peptide, its effect on DNA synthesis was examined. Serum-starved NIH 3T3 cells were treated with SA peptide, fixed, and the DNA concentration was determined by standard flow cytometric analysis. Specifically, confluent NIH 3T3 cells (1.3×10^6 cells) were serum-starved in DMEM containing 0.5% FBS for 2 days. The cells were untreated (control) or treated with SA peptide or aFGF for 20 h, harvested, spun down, and washed with serum-free PBS, three times. The cells were fixed with methanol precooled to -20°C for DNA analysis carried out by the Flow Cytometry Research Service of Vanderbilt University. The data were the mean \pm S.E.M. of six measurements and were analyzed for statistical significance by analysis of variance.

As shown in Table 2, the DNA synthesis in the S-phase of the cell cycle was significantly increased when the cells were treated with the SA peptide at $100 \mu\text{g/ml}$, which coincided with the active concentration in the thymidine incorporation assay (Fig. 1a). This result further confirms the role of the NLS region of aFGF in mitogenesis.¹⁸ Thus, these data also are consistent with a recent demonstration using a genetic approach that schwannoma-derived growth factor requires NLS to exert its mitogenic activity.²¹

TABLE 2

DNA SYNTHESIS STIMULATED BY SA PEPTIDE
AS COMPARED TO aFGF

Stimulus	Diploid % S Phase
Control	7.2 ± 0.7
SA (50 µg ml ⁻¹)	6.7 ± 0.9
SA (100 µg ml ⁻¹)	13.1 ± 0.5 (P < 0.05)
aFGF (15 ng ml ⁻¹)	27.8 ± 2.3 (P < 0.05)

However, compared with aFGF, the SA peptide is less mitogenically potent in both thymidine incorporation and DNA analysis assays (Fig. 1 and Table 2). aFGF binds to the FGF receptors on NIH 3T3 cells and induces the tyrosine phosphorylation of a number of intracellular proteins that have been suggested as the FGF receptor signalling substrates.^{22,23} In contrast, SA peptide did not stimulate the tyrosine phosphorylation of these intracellular proteins in the same cells even at the concentrations sufficient to induce DNA synthesis. Taken together, these results, make it unlikely that the mitogenic effect of SA peptide was mediated by FGF receptors.

20 Immunofluorescence Assay for Modified SA Peptide

The intracellular SA peptide could not be tracked by an immunofluorescence assay because it was not recognized by the available anti-SM peptide antibody. However, attaching two extra amino acid residues (Met-Pro) to the carboxyl terminus of the SA peptide produced a modified SA peptide (referred to as SA α , listed herein as SEQ ID NO:4) that contained a 3-amino acid epitope tag, Leu-Met-Pro, recognized by anti-SM peptide antibody in ELISA. Accordingly, intracellular SA α peptide was observed in a punctate staining pattern in the SA α -treated NIH 3T3 cells by an indirect immunofluorescence assay using anti-SM peptide antibody. Like SA peptide, SA α peptide was mitogenic in the thymidine incorporation assay. These results are consistent with the relationship between the SA peptides' import into the intracellular compartments and their mitogenic activity.

Membrane-Permeable Signal Peptide with Functional Peptide Cargo (SN50)

Having demonstrated the feasibility of the cellular import of membrane-permeable SM and SKP peptides, another functional cargo was attached to the amino-terminal hydrophobic sequence conferring membrane permeable capacity. For this purpose a sequence representing a functional domain of the nuclear factor κ B (NF- κ B) responsible for a nuclear localization signal was selected. Import of such a peptide into the cell would be measured by inhibition of nuclear translocation of NF- κ B complex in stimulated cells. The NF- κ B is a pleiotropic activator^{39,40} that plays a critical role in the regulation of a number of cellular and viral genes, including the enhancer of human immunodeficiency virus (HIV). The inactive cytosolic form of NF- κ B is a heterotrimer including p⁵⁰, p⁶⁵ and an inhibitory protein I κ B.^{41,42} Upon activation of cells with stimuli such as lipopolysaccharide (LPS) or cytokines,^{43,44,45} I κ B dissociates from the complex. This dissociation allows the translocation of heterodimer of p50 and p65 subunits to the nucleus. Both p50 and P65 subunits contain NLS, suggesting that the NLS sequence may be important for nuclear uptake of NF- κ B.

To determine the functional significance of the NLS of p50 and p65 subunits, two peptides were designed and synthesized containing the sequence motifs. The first peptide (referred to as SN50, listed herein as SEQ ID NO:9) contained the signal sequence of K-FGF^{16,17} at its amino-terminal region (residues 1-16) and a "functional cargo" in the form of NLS of NF- κ B p50 subunit at its carboxy-terminal region (residues¹⁷⁻²⁶). The second peptide is also a 26-residue peptide (referred to as SN65, listed herein as SEQ ID NO:8) that contains the same hydrophobic sequence and the NLS of p65 subunit. Both peptides were tested for their inhibitory effects on the nuclear translocation of the NF- κ B complex in LE-II cells. Inducible κ B binding activity was detectable by electrophoretic mobility shift assay in nuclear extracts from cells treated with LPS for 1 h.⁴³ However, this LPS-induced κ B binding activity in nuclear fraction was reduced substantially in the SN50 peptide-treated cells. The inhibition by SN50 peptide was concentration-dependent, reading an 88% inhibition at 50 μ g/ml. In contrast, no inhibition was observed in SN65 peptide-treated LEII cells. To exclude the possibility that the inhibition was caused by the interference of SN50

peptide in the binding of oligonucleotide probe to the NF- κ B complex, SN50 peptide was incubated *in vitro* with nuclear extracts and radiolabeled probe. This maneuver was without any measurable effect on LPS-induced κ B binding activity, suggesting that inhibition by SN50 peptide resulted from its action at the stage in which the active NF- κ B complex moves from cytosol to nucleus. To determine whether the inhibition by SN50 peptide required a hydrophobic, membrane-permeable sequence, two control peptides (SM and N50 peptides, listed herein as SEQ ID NOS: 1 and 10, respectively) were also tested in the same mobility shift assay. N50 peptide contained the NLS without the hydrophobic sequence, whereas SM peptide contained a hydrophobic sequence without the NLS. Neither of these two peptides showed any significant effect on LPS-induced intracellular translocation of the NF- κ B complex from the cytosol to the nucleus. These results suggest that neither the hydrophobic sequence alone (SM peptide) nor the nuclear localization sequence alone (N50 peptide) was sufficient for causing a functional inhibition of the NF- κ B. Therefore, the observed inhibitory effect of SN50 must be attributed to its intracellular import which allowed the interaction of its intrinsic NLS with the nuclear membranes.

SN50 peptide contained the same epitope tag as SM peptide and thus could be recognized by the anti-SM peptide antibody in ELISA. This allowed direct affirmation by an indirect immunofluorescence assay that SN50 peptide was imported into LE-II cells to exert its functional role. Results showed that the intracellular SN50 peptide was distributed in a more nuclear staining pattern as compared to the intracellular SM peptide.

25 EXAMPLE II

The efficacy of the intracellular inhibition of nuclear import of NF- κ B and other stress-responsive transactivators in abrogating *in vivo* changes resulting in lethal septic shock is based on the use of noninvasive intracellular delivery of the SN50 peptide containing a cell membrane-translocating sequence and NLS domain.⁵⁰⁻⁵² Two cell-permeable peptides, SM and SN50 were synthesized and purified as previously described,^{51,52} and first tested *in vitro* in two types of cells known to be a target for LPS:

murine macrophage J774 and endothelial LEII cell lines. (SM and SN50 peptides, listed herein as SEQ ID NOS: 1 and 9). The nuclear import of transcription factor NF- κ B induced by septic shock inducer, LPS (10 ng/ml) in murine J774 macrophages was blocked by SN50 peptide but not by SM peptide (both at 31 μ M). Whereas both
5 peptides are cell permeable, the SM peptide functional domain contains "loss of function" mutated NLS sequence.^{51,52} Similar pattern of results was obtained when J774 cells were stimulated with proinflammatory mediator of septic shock, TNF α (20 U/ml). The SN50 peptide also inhibited inducible nuclear import of NF- κ B in murine endothelial cells LEII stimulated with LPS (10 ng/ml) and TNF α (100 U/ml). Thus, the
10 SN50 peptide but not the SM peptide caused intracellular inhibition of inducible nuclear import of NF- κ B in murine macrophages and endothelial cells stimulated by LPS and TNF α .

The efficacy of the SN50 peptide-directed inhibition of NF- κ B and other stress-
15 responsive transactivators in attenuating or preventing in vivo septic shock was demonstrated by injecting C57BL/6 mice intraperitoneally with D-galactosamine (20 mg) followed by LPS from E.coli serotype 0127:B8 (1 μ g). Mice treated with D-galactosamine are sensitive to low doses of LPS.⁶⁰ As shown in Figure 2A all but one mouse showed symptoms of acute illness within 4 hours and died within 6 hours
20 following injection of LPS. In contrast, as shown in Figure 2C, mice treated with the SN50 peptide (5 injections up to 3 ½ h after LPS) showed no symptoms of shock and survived the first 24 h. By 48 h, 50% mice survived and by 72 h 20% survival was observed. The protective in vivo effect is dependent on functional NLS domain of the SN50 peptide, because it was abrogated when SM peptide with mutated NLS domain
25 was used. All SM peptide-treated mice (5 injections up to 3 ½ h after LPS) showed symptoms of acute illness and died within 5 h (Figure 2B). The in vivo protective effect of SN50 peptide was time-and concentration-dependent. Administration of SN50 peptide extended to 6 and 12 h following LPS (7 intraperitoneal injections) resulted in 64% survival at 72 h (Figure 2D). The differences in survival are
30 statistically significant with $P < 0.001$ based on the log rank test.⁶⁰

As this model of septic shock is characterized by fulminant liver injury, histopathologic analysis focused on the liver. Sections obtained from mice receiving lethal combination of D-galactosamine and LPS revealed diffuse hepatocellular injury with hallmarks of apoptosis (fragmented nuclei), engorgement of blood vessels filled with platelet thrombi, and extravasation of red blood cells. Identical pattern of massive apoptosis of hepatocytes accompanied by hemorrhagic liver necrosis was observed in mice treated with SM peptide. In contrast, tissue sections from the liver of SN50 peptide-treated mice that survived septic shock for 72 h, displayed almost normal liver architecture without any overt signs of apoptosis of hepatocytes and hemorrhagic necrosis. The simplest implication of these results is that intraperitoneal administration of the SN50 peptide provides significant cytoprotection of the liver, a primary target organ in murine model of D-galactosamine/LPS-induced septic shock.^{57,60}

These evidence that the SN50 peptide administered in vivo attenuates and/or prevents lethal septic shock induced by LPS. The microbial inducer of septic shock, LPS, acts on monocytes, macrophages, granulocytes, and endothelial cells that express multiple genes encoding proinflammatory cytokines (TNF α , IL-1, 6, 8, and 12), signal transducers (iNOS and COX2), cell adhesion molecules (E-selectin, VCAM, ICAM) and procoagulant molecules (Tissue Factor, Plasminogen Activator Inhibitor).^{48,49,67,68} Persistent expression of stress-responsive gene products changes the quiescent phenotype of blood cells and vascular endothelium into an "activated" phenotype and contributes to irreversible vascular dysfunction and leads to the ultimately fatal outcome.^{47,49} NF- κ B is a primary intracellular mediator of signaling to the nucleus induced by LPS in humans and mice wherein persistent nuclear translocation of NF- κ B correlated with lethal outcome.⁴⁹ Unlike extracellular LPS inhibitors or cytokine receptor antagonists, the SN50 peptide blocks the pre-final obligatory step in intracellular signaling to the nucleus by NF- κ B and other stress-responsive transactivators, regardless of the initiating stimulus.^{50,52}

The in vivo mechanism of protective action of the SN50 peptide can be deduced from these studies. First, the SN50 peptide is likely to attenuate NF- κ B-dependent

expression of cytokines and other stress-responsive gene products contributing to cellular and molecular pathogenesis of septic shock. The inhibitory effect of the SN50 peptide on expression of genes regulated by NF- κ B and other transactivators was demonstrated.⁵² Second, it is unlikely that the primary cellular site of action of the SN50 peptide are LPS-stimulated peritoneal macrophages because they do not appear to be the major cells responsible for the overall host response during endotoxic shock.⁶⁹ Rather, we have proven that the SN50 peptide exerts its protective effect systemically being absorbed from peritoneal cavity and crossing plasma membrane of vascular endothelial cells as well as of blood monocytes and tissue macrophages. Therein, it reaches its intracellular target, importin - α and - β heterodimer (also called karyopherin - α and - β) shuttling NF- κ B, AP-1, NFAT and STAT1 to the nucleus.⁵² Significant cytoprotective effect in the liver and overall gain in survival following repeated intraperitoneal administration of the SN50 peptide indicate its systemic in vivo effect. Third, the observed in vivo cytoprotective effect of the SN50 peptide in the liver is remarkable in the context of the reported Janus-like role of NF- κ B in preventing and inducing apoptosis.⁶³ Time-dependent anti-apoptotic effect of the SN50 peptide in the liver indicates that LPS and proinflammatory cytokine mediators, eg. TNF α and interferon γ , cannot induce apoptosis when nuclear import of NF- κ B, AP-1, NFAT and STAT-1 is blocked by the SN50 peptide as previously demonstrated.⁵² Other studies using genetically-engineered mice have provided significant insight in molecular mechanism of LPS-induced septic shock by pinpointing LPS receptors, cytokine receptors, and intracellular caspases as essential molecular mediators of septic shock.^{54-59,70-73}

25 Methods

Animals and Treatment

C57BL/6 mice were obtained from the Jackson Laboratory. 10-12 wk old female mice were injected intraperitoneally with 0.2 ml suspension of LPS from E. coli 0127:B8 (prepared by phenol extraction and gel filtration chromatography, Sigma Chemical Co.). D-galactosamine (20 mg in 0.2 ml; Sigma Chemical Co.) was injected intraperitoneally 30 minutes before LPS. Cell permeable SN50 and SM peptides (2 mg each in 0.2 ml) or 0.9% saline (diluent) were injected 30 min before and 30, 90, 150,

210 min after LPS. Additional intraperitoneal injections of the SN50 peptide to the survivors were administered 6 and 12 h after LPS. All injected agents were sterile and prepared in pyrogen-free saline for injections. Animals were observed at 2 h intervals during the first 12 h, at 4 h intervals during the subsequent 12 h and twice daily thereafter. Tissue sections from the liver, spleen, lungs, and kidneys were examined. Mice receiving either D-galactosamine (20 mg) alone (n=5) or LPS (1 µg) alone (n=5) survived and were unaffected on the basis of tissue sections from the principal organs. Animals were handled and experimental procedures were conducted in accordance with the American Association of Accreditation of Laboratory Animal Care guidelines and approved by the Institutional Animal Care Committee.

Cell-permeable peptides

The SN50 and SM peptides were synthesized, filter-sterilized, and analyzed as described.^{51,52}

Cell Cultures

Murine macrophage RAW 264.7 cell line obtained from the American Type Culture Collection (Rockville, MD) and murine endothelial (LEII) cells obtained from Dr. T. Maciag (Maine Medical Center, Portland, Maine) were cultured in Dulbecco Minimal Essential Medium supplemented with 10% heat-inactivated fetal bovine serum containing no detectable LPS (<0.006 ng/ml as determined by the manufacturer, Atlanta Biological, Norcross, GA), 2mM L-glutamine and antibiotics as recommended by ATCC. Where indicated, 5 ml of RAW 264.7 or LEII cells (10⁶/ml) were stimulated with LPS from Escherichia coli 0127:B8 (Difco) or TNFα with the potency of 32,000 U per µg (Mallinckrodt) at concentrations and tissue indicated in the text.

Electrophoretic mobility gel shift assay (EMSA)

To measure nuclear import of NF-κB in RAW 264.7 and LEII cells, EMSA was performed as described using a radiolabeled κB probe.^{51,52}

Statistical analysis The log rank test was used to determine P values for mouse survival data.⁶¹

EXAMPLE III

5 In this experiment, the effectiveness of this class of cell-permeable peptides in vitro with murine macrophages and endothelial cells was measured using SN50, carrying a nuclear localization sequence (NLS) derived from NF- κ B1 (p50), SM, were synthesized and purified as previously described,^{51,52} and a third cyclic peptide (cSN50) was designed by inserting two cysteines flanking NLS motif to form an intrachain
10 disulfide bond. (cSN50 peptide, listed herein as SEQ ID NO: 12) All three peptides are cell-permeable, but the SM peptide functional domain contains a mutated NLS that is not recognized by importin α (also called karyopherin α or Rch 1).⁵² In murine J774 macrophages, nuclear import of NF- κ B in response to LPS (10 ng/ml) was blocked by SN50 but not SM (both at 100 μ M). Similar results were obtained when J774 cells
15 were stimulated with TNF α (20 U/ml), a proinflammatory mediator of septic shock. The SN50 peptide also inhibited inducible nuclear import of NF- κ B in murine endothelial LEII cells stimulated with LPS (10 ng/ml) and TNF α (20 U/ml). The third peptide, cSN50 containing a cyclized NLS domain, was inhibitory at a concentration of 10 to 30 μ M. Based on quantitative phosphoimager analysis of these results, the
20 potency of cSN50 is 3-10 times greater than the prototypical SN50 peptide. Thus, cell-permeable peptides inhibited nuclear import of SRTFs in endotoxin-responsive cells in vitro.

 cSN50 was tested in vivo using a murine model for lethal endotoxic shock.⁶⁰ In
25 this model, LPS from E. coli serotype 0127:B8 (LD₁₀₀=800 μ g) was injected intraperitoneally into C57BL/6 mice. As shown in Figure 3A, all animals died within 72 hrs following LPS injection. In contrast, mice treated with cSN50 (0.7 mg given in 7 injections 30 minutes before to 12 hrs after LPS challenge) were protected from septic shock as evidenced by the lack of its typical signs (piloerection, lethargy,
30 diarrhea, hemorrhagic conjunctivitis, hemorrhagic skin necrosis, and paralysis). During subsequent 24 hrs 1 animal died and after 48 hrs 4 died, yielding a 50% survival rate

(Figure 3B). The protective effect of cSN50 was improved when the dose was increased to 1.5 mg per injection (Figure 3C). All but one animal survived for 72 hrs (90% survival). Survivors observed for the subsequent 10 days showed no apparent signs of disease. This *in vivo* protective effect was lost if the functional NLS motif was mutated as in the SM peptide. All SM peptide-treated mice died within 72 hrs (Figure 3D). Based on the log rank test, the difference in survival rate between cSN50 peptide-treated groups and controls was statistically significant ($p < 0.001$). Histologic examination of excised organs (lungs, liver, spleen, and kidneys) showed minimal changes in cSN50 peptide-treated survivors whereas untreated mice dying from endotoxin showed particularly prominent distention and engorgement of pulmonary vessels.

Prior studies have shown that following injection of LPS into humans and animals there is an early burst of proinflammatory cytokine mediators of septic shock such as $\text{TNF}\alpha$, IL-1, and $\text{INF-}\gamma$.⁽⁷⁵⁾ To determine whether the cSN50 peptide reduces lethality when administered after exposure to endotoxin, the first peptide dose was given 30 min after endotoxin. The survival rate was 60%, indicating that the cSN50 peptide may exert its protective effect, if given shortly after exposure to endotoxin. Taken together, cSN50 peptide protected mice from endotoxin-induced lethal shock in a time and concentration-dependent manner. Increasing the dose of injected peptide and/or number of injections improved survival rate. The requirement for repeated administration of cell-permeable peptide indicates that its protective effect is transient; reducing the number of injections lowers the survival rate consistent with a relatively short intracellular half-time (~45 min) of SN50.⁵⁰ Thus, the rapidly reversible effect of cell-permeable peptide accounts for its short-term effectiveness and safety. No lethality or tissue injury was observed in animals receiving peptide alone.

The efficacy of the cell-permeable peptide described in this study likely reflects *in vivo* inhibition of signaling to the nucleus mediated by SRTFs.^{51,52} In the absence of nuclear import inhibitor, SRTFs potently stimulate transcription of the genes encoding pro-inflammatory mediators of lethal shock.^{48,68,77} In turn, the persistent expression of

these genes in monocytes, macrophages, granulocytes, and endothelial cells is associated with profound vascular dysfunction and death.^{48,49,57,68,77} The inhibitory effect of the SN50 peptide on the expression of genes regulated by NF- κ B and other SRTF has been demonstrated.⁵² The finding that the cell-permeable peptides carrying NLS inhibit nuclear import in vitro shows that they can prevent LPS-induced activation of these inflammatory stress-responsive genes in vivo. Consistent with this, mutations that inactivate NLS function yield a cell-permeable peptide (SM) that fails to affect the acute systemic inflammatory response to endotoxin.

These experiments provide a conceptually novel approach to treatment of endotoxic shock. In contrast to extracellular inhibitors of LPS or cytokine receptor antagonists,⁷⁵ nuclear import inhibitors of SRTFs are targeted intracellularly.⁵⁰ The multiple proinflammatory agonists, eg LPS and cytokines, upon binding to their cognate receptors, initiate a cascade of signaling steps converging at the common step of nuclear import of SRTFs.^{48,54-58,68,77} Reversible inhibitors of nuclear import exemplified by cSN50 constitute a new class of anti-inflammatory agents capable of suppressing a systemic inflammatory response. Consistent with this approach, the SN50 peptide was effective in blocking lethal shock induced by superantigen, staphylococcal enterotoxin B, interacting with murine T lymphocytes.⁷⁶ In conclusion, our results with the NLS peptide functioning as nuclear import inhibitor provide a new, effective, and convenient in vivo targeting strategy to reduce morbidity and mortality in the systemic inflammatory response syndrome exemplified by endotoxic shock.

Methods

Animals and Treatment.

C57BL/6 mice were obtained from the Jackson Laboratory. 8-12 wk old female mice (20 g weight) were injected intraperitoneally with 0.2 ml suspension of LPS (800 μ g) from E. coli 0127:B8 (Difco, Detroit, MI). Cell-permeable cSN50 and SM peptides or 0.8% saline (diluent) were injected 30 min before and 30, 90, 150, 210 min, 6 hrs and 12 hrs after LPS. In some experiments cSN50 peptide was not injected before LPS. All injected agents were sterile and prepared in pyrogen-free saline.

Animals were observed at 2 h intervals during the first 8 h, at 4 h intervals during the subsequent 16 h, and twice daily thereafter. Autopsies were performed shortly after death or after sacrifice at 72 hours. Surviving animals were observed for 10 days.

Animals were handled and experimental procedures were conducted in accordance with the American Association of Accreditation of Laboratory Animal Care guidelines and approved by the Institutional Animal Care Committee.

Cell-permeable peptides

The SN50 and SM peptides were synthesized, filter-sterilized, and analyzed as described.^{11,12,51,52} The cSN50 peptide was synthesized and analyzed in a similar manner.

Cell Cultures

Murine macrophage J774 cell line was obtained from the American Type Culture Collection (Rockville, MD) and murine endothelial (LEII) cells were kindly provided by Dr. T. Maciag (Maine Medical Center, Portland, Maine). Both cell lines were cultured in Dulbecco Minimal Essential Medium supplemented with 10% heat-inactivated fetal bovine serum containing no detectable LPS (<0.006 ng/ml as determined by the manufacturer, Atlanta Biological, Norcross, GA), 2mM L-glutamine and antibiotics. Where indicated, 80% confluent monolayers of J774 or 100% confluent LEII cells (100mm plates with 10 ml fresh medium) were stimulated with LPS from Escherichia coli 0127:B8 (Difco) or with TNF α (32,000 U per μ g; Mallinckrodt) at concentrations and time indicated in the text. Nuclear import of NF- κ B in J774 and LEII cells was measured by Electrophoretic mobility gel shift assay (EMSA) using a radiolabeled κ B probe.^{6,7}

Electrophoretic mobility gel shift assay (EMSA)

Measurement of the nuclear import of NF- κ B was performed as described using a radiolabeled κ B probe.^{51,52}

Histologic analysis

Formalin-fixed, paraffin-embedded sections of the liver, spleen, lungs, and kidneys were stained with hematoxylin and eosin to assess overall histology.

Statistical analysis

5 The log rank test was used to determine P values for mouse survival data.⁶¹

At the molecular level, systemic inflammatory response syndromes such as endotoxic shock are mediated via nuclear signaling of NF- κ B and other stress-responsive transcription factors (SRTFs), which regulate the expression of septic shock
10 mediators.^{48,49} These findings demonstrate the in vivo utility of cell-permeating peptide inhibitor of NF- κ B in the therapeutic control of an acute systemic inflammatory response at the level of nuclear signaling. Inhibition of nuclear import of SRTFs with a cyclic cell-permeable peptide demonstrates a new approach to the control of systemic inflammatory response syndromes such as endotoxic shock.

15

Septic shock triggered by endotoxic lipopolysaccharide (LPS) is an extreme form of the systemic inflammatory response syndrome that is characterized by collapse of the circulatory system, disseminated intravascular coagulation, and multiple organ failure resulting in high morbidity and mortality.^{46,47} Treatment of septic shock is often
20 ineffectual, as diverse mediators lead to fatal outcome.^{53,66} These mediators are expressed because SRTFs relay signals to the nuclei in endotoxin-responsive cells (monocytes, macrophages, endothelial cells).^{48,68,77}

There is abundant evidence that SRTFs, reaching the nuclei from the cytoplasm,
25 activate genes encoding proinflammatory cytokines such as, tumor necrosis factor α (TNF α), interleukins 1,6,8,12,18, cell adhesion molecules, ICAM-1, E selectin and VCAM, as well as the procoagulant molecules, tissue factor and plasminogen activator inhibitor.^{48,68,77} The SRTFs, mediating responses to inflammatory and immune stress are NF- κ B, AP-1, NFAT and STAT-1.^{48,49,57,67,68,77} For example, NF- κ B and NFAT
30 regulate genes encoding primary cytokine mediators of septic shock, TNF α and

interferon γ (INF- γ).⁷⁴ The gene encoding tissue factor, a primary procoagulant mediator of disseminated intravascular coagulation, is regulated by NF- κ B and AP1.⁶⁸

In humans and mice, persistent nuclear translocation of NF- κ B in mononuclear
5 phagocytic cells correlated with lethal outcome of septic shock.⁴⁹ Nuclear import of these transactivators can be blocked by non-invasive intracellular delivery of SN50 peptide bearing a membrane translocation motif and a functional domain comprised of the nuclear localization sequence (NLS) derived from NF- κ B and recognized by heterodimer of importin α and importin β (also called karyopherin - α and - β).⁵⁰⁻⁵² These
10 in vivo findings present a novel approach to the therapeutic control of lethal septic shock involving the delivery of cell-permeable peptides that affect nuclear targeting of NF- κ B and other stress-responsive transactivators.

Example IV: Inhibition of superantigen-induced toxic shock and acute liver injury
15 **by a cSN50 peptide**

Bacterial superantigens (SAGs) are exotoxins produced by Gram-positive bacteria such as staphylococci and β -hemolytic streptococci. These toxins, which include staphylococcal enterotoxins, Toxic Shock Syndrome Toxin-1, and streptococcal pyrogenic exotoxins, induce Toxic Shock Syndrome in humans and in animals. SAGs
20 released as a consequence infection by Gram-positive bacteria can stimulate a relatively large percentage (about 10-50%) of all T cells in the body of the infected individual, and activation of these T cells leads to systemic cytokine production (TNF- α , IL-2, IFN- γ). Such SAG-induced activation of T cells requires the presence of antigen presenting cells (APC) expressing class II MHC molecules. The resultant systemic
25 inflammatory response is characterized by desquamation, vascular injury, hypotension, and disseminated intravascular coagulation (DIC). Together, these effects produce lethal toxic shock; mortality due to staphylococcal-induced Toxic Shock Syndrome is about 5%, and mortality due to streptococcal-induced Toxic Shock Syndrome is about 30-80%.

At the molecular level, T cell signaling to the nucleus via the T cell receptor/CD3 complex induces pro-inflammatory cytokine expression. This signaling is mediated by NF- κ B and other stress responsive transcription factors (SRTF), including AP1 and NF-AT. The NF- κ B p50/p65 heterodimer is complexed with the inhibitory protein, I κ B. Cellular activation results in phosphorylation and then degradation of I κ B, thereby releasing the NF- κ B p50/p65 heterodimer for import to the nucleus. AP-1 proteins, c-Fos and c-Jun, are present at low levels in resting T cells. De novo protein synthesis is followed by nuclear import of c-Fos and c-Jun. NF-AT is a phosphoprotein in the cytoplasm of resting T cells. Activation of T cells induces its dephosphorylation and nuclear import. NFAT binds to DNA alone or in complex with c-Fos and c-Jun. The transcription factors enter the nucleus, bind to the promoters of pro-inflammatory genes and induce expression of cytokines, such as TNF- α , IL-2, and INF- γ . The newly expressed TNF- α binds to its receptor and induces another cycle of activation. Thus, inhibition of nuclear import of NF- κ B and other stress-responsive transcription factors by a cell-permeable peptide analog of the NF- κ B nuclear localization sequence (NLS) can suppress expression of genes that encode mediators of toxic shock.

To study the effect of the cSN50 peptide on NF- κ B nuclear import in natural killer T (NK-T) cells, we incubated dendritic cells (DC) with staphylococcal enterotoxin B (SEB) for 60 min at 37 °C and separately incubated NK-T cells with cSN50 peptide for 30 min at 37 °C, then mixed 95% of NK-T cells with 5% of DC and incubated the cell mixture for 2 hrs at 37 °C. After incubation, nuclear extracts were prepared and analyzed by electrophoretic mobility shift assay (EMSA) using a probe containing a binding site for NF- κ B. SEB-stimulated NK-T cells displayed high levels of NF- κ B translocation to the nucleus, as evidenced by a strong EMSA signal, compared with unstimulated cells, as evidenced by very low levels of NF- κ B binding to the probe (Fig. 4; compare first and second lanes). Increasing concentrations of the cSN50 peptide (from 3 to 30 μ M) resulted in increasing inhibition of SEB-induced NF- κ B nuclear import (Fig. 4; see third through fifth lanes). As a control, included in all EMSA reactions was a probe containing a binding site for NF-Y, a constitutively

expressed nuclear protein. This control shows equal loading of the lanes shown in Fig. 4. These results indicate that the cSN50 peptide inhibited NF- κ B nuclear import in NK-T cells.

5 We next established a murine model of SAg-induced toxic shock, which involves administration of staphylococcal enterotoxin B (SEB) (300 ug) to C57Bl/6 mice (wild type), together with D-galactosamine (20 mg) as a sensitizing agent. To study the development of toxic shock, we monitored the expression of the pro-inflammatory cytokines TNF- α and IFN γ , mouse survival rate, and histology. To study
10 the *in vivo* effect of cSN50 peptide on toxic shock development, we used wild type mice, given 7 injections IP with 0.7 mg cSN50 peptide. The schedule for cSN50 peptide treatment was 30 min before SEB and after SEB challenge at 30, 90, 150, 210 mins, 6 hr, and 12 h (Fig. 5). As a negative control, we injected additional mice with the inactive cell-permeable peptide SM (described above), which has a mutated NLS
15 sequence. The peptide-injected mice were observed for signs of illness and/or survival for 72 h.

The SEB-challenged, cSN50 peptide-treated mice displayed a survival rate of 80% (Fig. 5). By contrast, the SEB-challenged, SM peptide-treated mice displayed a
20 survival rate of only 10%, similar to that of SEB-challenged mice not treated with peptide. These results show that the cSN50 peptide protects mice from SEB-induced toxic shock.

The most striking feature of this model of toxic shock is acute liver injury with
25 apoptosis and hemorrhagic necrosis (Fig. 6A-6D). The left panels (Figs. 6A and 6D) show liver sections from untreated control mice challenged with SEB, stained with hematoxylin and eosin and Apop Tag (Intergen, Purchase, NY), respectively, reveal extensive hemorrhage and apoptosis. In contrast, liver sections from cSN50 peptide-treated mice challenged with SEB, shown on the right (Figs. 6B and 6D), display no
30 detectable signs of liver injury or apoptosis, indicating that the cSN50 peptide provided

effective protection from the inflammatory effects induced by a SAg from a Gram-positive bacterium.

Example V: Methods for producing cyclized peptides

5 Selected peptide sequences of the type X_1 - X_2 , wherein X_1 contains a membrane-permeable motif, and X_2 contains a nuclear localization sequence (NLS), can be flanked by two cysteine residues either as: X_1 -Cys X_2 -Cys or Cys X_1 - X_2 -Cys. Such positioning of the cysteine residues allows efficient disulfide bond formation and cyclization of either the functional segment (X_2) or the entire bipartite peptide (X_1 - X_2). Alternatively, 10 lactam or lactone cyclization can be performed by substituting cysteine at the N-terminus of X_2 with serine (lactone) or with diaminopropionic acid (lactane). As shown in Example III above, constraint of the biologically active segment (containing, e.g., a nuclear localization sequence, enhances the activity of the peptide. Moreover, the degradation rate of cyclic peptides is distinctly slower than that of linear peptides, 15 because the breakdown of a peptide chain proceeds most readily from either the amino or carboxy terminus.

Another approach to cyclization of NLS-containing peptides is based on a solid-phase intramolecular chemical ligation strategy to synthesize cyclic thioester peptides 20 via thiolactone ring formation. A fully unprotected peptide is immobilized on a solid support through a reactive thiol ester bond. Preloaded t-butoxycarbonyl-aminoacyl-3-mercapto-propionamide-polyethelene glycol-poly-(N,N-dimethylacrylamide) (Boc-AA-[COS]-PEGA) resin is used for synthesis (Camarero, J.A., et al., *J. Pept. Res.* 51:303-316, 1998 and Schnöülzer, M. et al., *Int. J. Pept. Protein Res.* 40:180-193, 1997) 25 Peptide-[COS]-PEGA resin is treated with HF for 1 hr at 4 °C to obtain fully unprotected peptide. Such an unprotected peptide-[COS]-PEGA resin, containing an ester linkage which anchors peptide to resin, is stable in anhydrous HF and can be then selectively cyclized and simultaneously cleaned from the resin by its swelling in aqueous buffer (0.1 M sodium phosphate, pH 7.0 and acetonitrile in the ratio 80:20). 30 After washing the resin with 0.1% TFA in water, the cyclized peptide is purified by reverse-phase HPLC.

Still another strategy for peptide cyclization is based on the general method of "backbone cyclization" (Gilon, C. et al. *Biopolymers* 31:745-750, 1991) in which the connection of the N^α or C^α atoms in the peptide backbone to each other or the carboxyl and amino termini provide a constrained conformation of biologically active peptide segment.

In general, peptides are synthesized using either N-tert-butoxycarbonyl (t-Boc) or the N-9 fluorenylmethoxycarbonyl (Fmoc) strategies. Cysteine residues can be protected with acetaminidomethyl (Acm). Boc deprotection is performed with 50% trifluoroacetic acid (TFA) in dichloromethane (DCM). Fmoc deprotection is performed with 20% piperidine in DMF for 30 min and repeated twice each time. Peptides from Fmoc synthesis are cleaved from the resin by TFA/thioanisole/triisopropylsilane/methanol (90:5:2.5:2.5;vol/vol/vol/vol) at 20°C for 4 hrs. Peptides from Boc synthesis are cleaved by anhydrous fluorhydric acid (HF)/anisole (9:1 vol/vol) at 4EC for 1-2 hr and the crude peptides are precipitated with cold ethyl ether, dissolved in 60% acetonitrile in H₂O and lyophilized. Peptides are dialyzed against water using a Spectra/Por CE dialysis membrane (molecular weight cut off: 500) and chromatographed on high pressure liquid chromatography. A reverse phase (HPLC) column (Vydac C-18; 0.045% TFA in water/acetonitrile gradient). The bis (Acm)-Cys protected peptides can be cyclized, e.g., in 8:1 acetic acid/water with iodine as described (Kamber, B. et al., *Helv. Chem. Acta* 63:899-915, 1980). The completeness of cyclization can be assessed by electrospray mass spectrometry (loss of Acm groups) and a negative Ellman's test. The purified peptides are analyzed by analytical HPLC, matrix-assisted laser desorption ionization mass spectroscopy (MALDI-MS), and amino acid analysis.

Example VI: Inhibition of NF-κB nuclear import by D-amino acid-substituted MPS-NF-κB peptides

The fundamental mechanism underlying the transport of functional peptides across plasma membrane barrier remained unexplained. While not wishing to be bound by theory, we hypothesized that the intracellular delivery of our cell-permeable

peptides across the plasma membranes of multiple cell types involves translocation through the membrane phospholipid bilayer, rather than receptor-or transporter-specific recognition and uptake. To test this hypothesis, we synthesized, purified, and tested the enantio-inverso (all D-amino acids) analog of a hydrophobic motif signal sequence, which we had previously designed as a membrane-permeable sequence (MPS).

MPS based on the hydrophobic region of the signal sequence of Kaposi Fibroblast Growth Factor (KFGF), as described above, was synthesized with all L- or all D- amino acids to establish whether the import is dependent on chirally-specific receptor or membrane transport. All L- or its "mirror image" all D-MPS was coupled to functional domain ("cargo") containing nuclear localization sequence (NLS) of Nuclear Factor- κ B (NF- κ B). Such a peptide inhibits NF- κ B signaling to the nucleus by competitive inhibition of cytoplasmic/nuclear translocation mechanism. Both isomers of MPS were able to deliver NLS to cytoplasm of murine endothelial LE II cells (Fig. 7A) and human erythroleukemia cells (Fig. 7B), as evidenced by concentration-dependent inhibition of nuclear import of NF- κ B induced by proinflammatory agonists LPS (Fig. 7A) and TNF- α (Fig. 7B). Thus, intracellular delivery of functional peptides is not dependent on chirality of MPS, indicating that a specific receptor or transporter protein is not involved. Moreover, MPS made of all D-amino acids renders this part of imported peptides resistant to peptidases.

Example VII: Inhibition of inflammatory skin reaction by the cell-permeable SN50 peptide

Proinflammatory agents in contact with the skin cause localized inflammatory reactions. For example, such a reaction can be elicited by bacterial lipopolysaccharide (*Salmonella typhosa* LPS 200 μ g/ml in sterile, pyrogen-free saline) which is applied first to rabbits as an intradermal injection (preparatory dose). To elicit localized inflammatory reaction at the site of the first injection, a second injection of LPS (100 μ g/kg body weight) is administered within 18-24 hours intravenously into a rabbit ear vein. Subsequently, usually after about 4 hrs, a change at the site of initial skin injection is detected. It is manifested by a localized swelling due to increased vascular

permeability, redness due to vasodilation, and accumulation of white blood cells and platelets in the skin blood vessels. This reaction, termed "localized Shwartzman reaction," can be visualized by intravenous injection of a biologic dye such as Evans' Blue. Thus, a positive reaction is manifested at the skin site of the first LPS injection as a blue area of inflammatory reaction. Intradermal application of the cell-permeable peptide SN50, prior to the second LPS injection, reduced localized skin inflammatory reaction as reflected by a greatly diminished area of blue discoloration. When diluent alone (pyrogen-free saline solution) was administered as a negative control, the localized skin inflammatory reaction remained unchanged. Thus, the cell-permeable peptide SN50, applied topically to the skin, can reduce localized inflammatory reaction. This model or other known models of inflammatory skin disease can be used to further study the efficacy of cell-permeable peptides (for example, linear or cyclic peptides that contain an NF- κ B NLS, e.g., SN50 or cSN50) and to identify analogs of these peptides that inhibit inflammatory responses in skin. Such NF- κ B NLS-based peptides can be used to treat, prevent, or reduce the effects of inflammatory diseases and conditions of the skin involving autoimmune or allergic responses, for example, but not limited to, psoriasis, eczema, contact dermatitis (for example, due to contact with poison ivy or poison oak, nickel, latex, environmental toxins, or bacterial or fungal infections, i.e., those causing "athletes foot" or "jock itch"). The peptides can also be used to treat, prevent, or reduce the inflammatory effects of chemical or thermal burns to the skin.

Throughout this application, various publications are referenced. The disclosures of these publications in their entireties are hereby incorporated by reference into this application in order to more fully describe the state of the art to which this invention pertains.

Although the present process has been described with reference to specific details of certain embodiments thereof, it is not intended that such details should be regarded as limitations upon the scope of the invention except as and to the extent that they are included in the accompanying claims.

What is claimed is:

1. A method for treating or preventing an inflammatory response in a subject, comprising administering to the subject a peptide comprising an NF-kB nuclear localization sequence such that nuclear import of a stress-responsive transcription factor is inhibited in a cell of the subject, thereby treating or preventing an inflammatory response in the subject.
2. The method of claim 1, wherein the stress-responsive transcription factor is NF-kB, AP-1, NFAT, or STAT-1.
3. The method of claim 1, wherein the peptide further comprises a cell membrane-permeable hydrophobic region of a signal peptide.
4. The method of claim 3, wherein the cell membrane-permeable hydrophobic region of a signal peptide comprises a Kaposi Fibroblast Growth Factor signal peptide hydrophobic region having the amino acid sequence Ala-Ala-Val-Ala-Leu-Leu-Pro-Ala-Val-Leu-Ala-Leu-Leu-Ala-Pro.
5. The method of claim 3, wherein the cell membrane-permeable hydrophobic region of a signal peptide comprises an integrin beta-3 signal peptide hydrophobic region having the amino acid sequence Val-Thr-Val-Leu-Ala-Leu-Gly-Ala-Leu-Ala-Gly-Val-Gly-Val-Gly.
6. The method of claim 1, wherein the NF-kB nuclear localization sequence comprises the amino acid sequence Gln-Arg-Lys-Arg-Gln-Lys.
7. The method of claim 6, wherein the NF-kB nuclear localization sequence comprises the amino acid sequence Val-Gln-Arg-Lys-Arg-Gln-Lys-Leu-Met-Pro.

8. The method of claim 1, wherein the peptide is a cyclic peptide comprising a cell membrane-permeable hydrophobic region of a signal peptide and an NF-kB nuclear localization sequence comprising the amino acid sequence Gln-Arg-Lys-Arg-Gln-Lys.

9. The method of claim 1, wherein the peptide comprises a cyclized NF-kB nuclear localization sequence having the amino acid sequence Cys-Xaa-Xaa-Gln-Arg-Lys-Arg-Gln-Lys-Xaa-Xaa-Xaa-Cys, wherein Xaa is any amino acid.

10. The method of claim 9, wherein one or more amino acids of the cyclic peptide is a D-amino acid.

11. The method of claim 9, wherein the cyclic peptide has the amino acid sequence of cSN50.

12. The method of claim 1, wherein the inflammatory response is caused by a microbe or by a toxin from a microbe.

13. The method of claim 12, wherein the microbe is a Gram-negative bacterium or a Gram-positive bacterium.

14. The method of claim 1, wherein the inflammatory response is a systemic inflammatory response.

15. The method of claim 14, wherein the systemic inflammatory response causes septic shock.

16. The method of claim 1, wherein the inflammatory response is a localized inflammatory response.

17. The method of claim 1, wherein the localized inflammatory response is an inflammatory skin condition.

18. A method for treating or preventing septic shock in a subject, comprising delivering to the subject a compound comprising a peptide comprising a nuclear localization sequence of NF-kB such that nuclear import of NF-kB is inhibited, thereby treating or preventing septic shock in the subject.

19. The method of claim 18, wherein the peptide further comprises a cell membrane-permeable hydrophobic region of a signal peptide.

20. The method of claim 18, wherein the nuclear import of a member selected from the group consisting of AP-1, NFAT and STAT-1 is also inhibited.

21. The method of claim 18, wherein the nuclear import of each of AP-1, NFAT and STAT1 is also inhibited.

22. The method of claim 1, wherein the peptide is a cyclic peptide.

23. A method of importing a biologically active molecule into the nucleus of a cell in a subject comprising administering to the subject a complex comprising the molecule linked to a cell membrane-permeable hydrophobic region of a signal peptide and a nuclear localization peptide, thereby importing the molecule into the nucleus of the cell of the subject.

24. The method of claim 23, wherein the molecule is linked to a peptide comprising the amino acid sequence set forth in SEQ ID NO:12.

25. The method of claim 23, wherein the molecule is linked to a peptide comprising the amino acid sequence set forth in SEQ ID NO:13.

26. A method for treating or preventing a systemic inflammatory response in a subject, wherein the systemic inflammatory response involves import of a stress-

responsive transcription factor into the nucleus of a cell in the subject, comprising administering to the subject a peptide comprising a nuclear localization sequence of NF- κ B, thereby treating or preventing the systemic inflammatory response in the subject.

27. A method of inhibiting the import of a stress-responsive transcription factor into the nucleus of a cell, comprising administering to the cell a peptide comprising a nuclear localization sequence of NF- κ B, thereby inhibiting the import of the stress-responsive transcription factor into the nucleus of the cell.

28. The method of claim 27, wherein the cell is within a subject.

29. The method of claim 28, wherein the peptide is administered to the subject.

30. The method of claim 27, wherein the cell is a liver cell and wherein administration of the peptide to the liver cell inhibits apoptosis of the liver cell.

31. The method of claim 27, wherein the peptide is a cyclic peptide.

32. The method of claim 31, wherein the cyclic peptide comprises the amino acid sequence set forth in SEQ ID NO: 12.

33. A complex comprising a cell membrane-permeable hydrophobic region of a signal peptide linked to a biologically active molecule selected from the group consisting of a nucleic acid, a carbohydrate, a lipid, a glycolipid and a therapeutic agent.

INTERNATIONAL SEARCH REPORT

International application No.

PCT/US00/32516

A. CLASSIFICATION OF SUBJECT MATTER

IPC(7) : A61K 31/00, 38/00

US CL : 514/1,2

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

U.S. : 514/1,2,921

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)
Please See Continuation Sheet

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category *	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
X --- Y	US 5,877,282 A (NADLER et al.) 02 March 1999 (02/03/1999), see entire document, especially columns 3, 15 and 20 and SEQ ID NOs: 1 and 5.	1-4, 6, 7, 12-19, 26-29
Y	US 5,916,872 A (CHANG et al.) 29 June 1999 (29/06/1999), see entire document, especially column 2, lines 4-16.	5, 8-11, 20-22, 30-32
X --- Y	WO 98/11907 A1 (BRISTOL-MYERS SQUIBB COMPANY) 26 March 1998 (26/03/1998), see entire document, especially pages 5, 6, 38-39 and SEQ ID NOs: 1 and 5.	8-11, 22, 31, 32
X, P	LIU et al. Peptide-directed suppression of a pro-inflammatory cytokine response. Journal of Biological Chemistry. 02 June 2000, Vol. 275, pages 16774-16778, see entire document.	1-4, 6, 7, 12-19, 26-29
x --- y	QIN et al. Nuclear Factor-kB contributes to excitotoxin-induced apoptosis in rat striatum. Molecular Pharmacology. 1998, Vol. 53, pages 33-42, see entire document.	5, 8-11, 20-22, 30-32

		27-29
		8-11, 22, 30-32

☒ Further documents are listed in the continuation of Box C.

See patent family annex.

* Special categories of cited documents:

"A" document defining the general state of the art which is not considered to be of particular relevance

"E" earlier application or patent published on or after the international filing date

"L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)

"O" document referring to an oral disclosure, use, exhibition or other means

"P" document published prior to the international filing date but later than the priority date claimed

"T"

later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

"X"

document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

"Y"

document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art

"&"

document member of the same patent family

Date of the actual completion of the international search

INTERNATIONAL SEARCH REPORT

Int ional application No.

PCT/US00/32516

Box I Observations where certain claims were found unsearchable (Continuation of Item 1 of first sheet)

This international report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☐ Claim Nos.:
because they relate to subject matter not required to be searched by this Authority, namely:
2. ☐ Claim Nos.:
because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically:
3. ☐ Claim Nos.:
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box II Observations where unity of invention is lacking (Continuation of Item 2 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:
Please See Continuation Sheet

1. ☐ As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims.
2. ☐ As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.
3. ☐ As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims for which fees were paid, specifically claims Nos.:
4. ☒ No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.: 1-22 and 26-32

Remark on Protest

☐
☐

The additional search fees were accompanied by the applicant's protest.

No protest accompanied the payment of additional search fees.

INTERNATIONAL SEARCH REPORT

International application No.

PCT/US00/32516

BOX II. OBSERVATIONS WHERE UNITY OF INVENTION IS LACKING This application contains the following inventions or groups of inventions which are not so linked as to form a single general inventive concept under PCT Rule 13.1. In order for all inventions to be examined, the appropriate additional examination fees must be paid.

Group I, claim(s) 1-22 and 26-32 drawn to a method to treat/prevent inflammatory response by inhibiting nuclear import of a stress-responsive transcription factor.

Group II, claim(s) 23-25, drawn to a method to import a biologically active molecule into the nucleus of a cell.

Group III, claim 33, drawn to a complex comprising a signal peptide.

The inventions listed as Groups I, II, and III do not relate to a single general inventive concept under PCT Rule 13.1 because, under PCT Rule 13.2, they lack the same or corresponding special technical features for the following reasons: the special technical feature of Group I is that nuclear import of a transcription factor is inhibited. The special technical feature of Group II is that a biologically active molecule is imported into the nucleus of a cell. The special technical feature of Group III is that it is a molecule linked to a signal peptide.

Continuation of B. FIELDS SEARCHED Item 3: WEST: USPT, JPAB, EPAB, DWPI

STN: Medline, Caplus

search terms: nuclear, localization, translocation, import, prevent, inhibit, peptide, polypeptide, cyclic, inflammatory, sepsis, liver, apoptosis, NF-kB, NFAT, inventors' names
